Well you seem to be optomistic about America's future so why isn't
that reflected
in your daily tone?. Both you and Roy appear to be so unhappy with
those around you

as well as being sarcastic to all as we enjoy the hobby. It would be really great
if you shared your knoweledge of radiation in a way that would help those who
request it. You certainly have the knoweledge yet you seem to abhore the
pleasure that one obtains from giving to others. I know that you do not desire
the accumulation of money as does Roy so I feel you should re examine what your present
agender serves. Just think, you could provide insights on radiation that would dwarf
the never ending subjects of standing waves, current distribution on coils and yes
even discussion around the laws of the universe that would demand attention from
the inquisitive and draw them away from subjects that have already turned on their
twentyive circuit of arguments where people have forgotten their initial positions
and are now argueing against the same without challenge. Talk to us about the
trend towards short antennas or why radiation does not come from the end of a radiator,
or the difference between systems and antennas or comments with respect to old wives tails.
Frankly most of us are more interested in what is correct and right and you are
well placed in that area. Cheer up, have a life and enjoy it and savor the delights
of the hobby and of giving. We already have Roy as a self styled upper guru
so the last thing we need is a clone that dwells on the errors of others.
Have a happy holiday
Art

If you want evidence of transmission line behavior
look at the EZNEC files for:

http://www.w5dxp.com/travstnd.gif

One file is a coil terminated in its characteristic
impedance. The other is the same coil unterminated.

Based on your questions, an ordinary prudent man would
assume that you are just wasting my time. Next thing
is that you will be ragging on me for the number of
postings I had to make in answering your questions.

If you want transmission line behavior evidence in
coils, look at Corum's Figure 2 in section III of
his paper.

It's probably true that ideal transmission lines don't exist in any
form. The standing wave in question has both a minimum AND a maximum,
whose locations are determined by the relative phase and amplitude of
the forward and reflected waves at each position.

> The "current maximum" in
> the coil is caused by adjacent coupling between the

How do you propose that this occurs without having an effect on the
forward and reflected waves which comprise the standing wave?

What does the IEEE dictionary have to say about 'current humps' I wonder.

In that case, I apologize for jumping on you. The VF of
the coil is approximately double what it would be if
the current followed the wire. That's because of the
inter-winding interaction. But the magnetic fields
from coil#1 do not magically jump 10 inches to coil#100
as W8JI implies they do. His measurements are off by
a magnitude because he used standing-wave current for
his measurements. I suspect he actually measured less
than 3 ns "delay" but knew he couldn't afford to post
a faster-than-light measurement.

Art wrote:
"That is because you quote outdated technology and have lost the means of deduction for yourself."

O.K, Not much technical content in that posting, nor hint of what Art hopes to do with an 80 degree tilt. Maximizing horizontal polarisation is another mystery. Vertical polarization is the way to launch groundwaves and it will be so 100 years from today. Modern technology is unlikely to improve the FCC approved antenna and grounding systems used in AM broadcasting, thanks to RCA`s B., L., & E. (1927).

The coil argument has persisted a long time but it has provoked some searching into the behavior of inductance. W8JI may be on to something but he may not have it exactly right. Terman and Lenkurt have the TWT down, as invented in England (1943) but its coil is stretched out so that a foot long coil only has a dozen turns and lacks tight coupling which might work as W8JI describes.

Best regards, Richard Harrison, KB5WZI

I can do that, Tom, but I am standing by for an emergency
trip to New York which involves my daughter's life.

In the meantime, let's see if we can agree if 43.4 degrees
of 600 ohm line is terminated in -j567 ohms, the forward
current will be in phase with the reflected current, i.e.
the impedance looking into the line will be zero ohms. Have
you used any current reflection coefficients recently? :-)

That worked with Windows 98 and SE. Doesn't work
with XP. When I go to paste into paint, there is
nothing there to paste. The problem is that XP
won't allow me to display MicroSmith in a window.

It obviously has an effect on the standing wave. In no
way can Wes's current waveform be called a cosine function.
However, we know that the current and voltage are in
phase at the feedpoint and at the tip of the antenna.
It is impossible for them to be in phase anywhere else.

> It would be better if you provided some sort of demarcation between the

Obviously. The question is, how to reconcile that fact with your
statement:

> "A loading coil is not an ideal
> transmission line and its "current maximum" is not
> caused by standing waves."

A current maximum would obviously be a prominent feature of standing
waves resulting from the superposition of forward and reflected currents.

> In no
> way can Wes's current waveform be called a cosine function.

Wes who?

> However, we know that the current and voltage are in
> phase at the feedpoint and at the tip of the antenna.

Assuming it's a resistive antenna, assuming we're talking about
forward current. What other assumptions are we missing?

> It's all simple physics, Jim, aided by a measured IQ of 168.

;-) There.
Among the things evidently manifested by an alleged "IQ of 168" are a
narcisitic overestimate of ones own abilities and a compulsive need to
demonstrate same.

What does "its current maximum is not caused by standing waves" mean
to someone with an "IQ of 168"?

Yes, I have seen it time and time again ... people are fired for proficiency, IQ, skills, warm personalities, etc. I have seen gifted individuals sabotaged, setup, conspired against, etc. Has made me very slow to react on job performance evaluations given by others on an individual(s.)

The idiots of the world have a mission and a lot at stake, they will "kill" competition on sight! This is used as a strong "survival skill" by them ... convince the nephew that there is a lot to be had by "dummying up" at the correct times and places.

Sometimes you wonder if this is not the major force at work in large corporations?

I don't know the Midland Full Band T 734 antenna.
But, if it's a discone, any cutting you might due will only affect its
minimum low frequency spec. It'll be 'good', then, from that freq on up
for several octaves -- for slelected definitions of 'good'.

> is another mystery.

Hmm You put a stake in the ground when you stated that you can take
Kraus to the bank. Have you changed your mind regarding a tilt angle?
Why do you state that maximising horizontal polarisation is a mystery
if you are now finally aware of antenna tilt?
As far as maximising specific polarisation apparently airports need
to devise such a system to find wind shear systems. I suspect that
medical systems would appreciate a clearer focus. But describing
this effect to fill a hole that is present in industry it is just
something that was revealed when adding time varient and radiators
to Gaussian law. It forced me to consider the equilibrium effects
within the arbitary gravitational field which thus demanded a full
wave length radiator and not to accept fractional lengths.
The same trail also showed me that an array in equilibrium provides
stacked gain tho using a single feed and again the tilt angle comes
into play. These determinations along the path of the trail showed
that the helix angle that Kraus found by experimentation was a
reflection of the radiator tilt revealed while on the trail.
This tilt angle is given by all computor programs some thing I
was unaware of and where all people on this group are in denial.
The same trail leads to helix antennas that are in equilibrium
which by following the trail provides me with a rotatable
directive antenna which also provides a path to a near point
radiation system predicted by a russian scientist as being
possible. What I intend to do with the radiator tilt is of no
concern to me or that the trail's final destination is
Maxwell's law which is thus now described in deeper detail.
This emphasises that old chinese saying It is n ot the
destination that counts but the journey taken to get there.
You can mock the idea of a tilt and any program that portrays
it but for the young and inquisitive it is quite exciting.
When we are gone and forgotten new wheels will roll on
this same trail and there will be an understanding as how the
Japanese did not have a yagi antenna during the last war.
This was the unwillingnes to change despite the obvious.

If you haven't got a computor or unwilling to address
computor programs then ask a friend to check it out for you.
Adding this to Terman could possibly allow you to leapfrog
the world with respect to radiation.Or you can ignore it and
pass on restfully and without concern to your final destiny.
Your choice

Materials do not radiate electromagnetically. Dynamic fields cause
radiation. It does not take an experienced physicist such as yourself to
know that.

> Are they all of a specific type?

A plastic ping pong ball can be used to radiate a TEM as long as you apply a
static electricity charge to it and apply kinetic energy by moving it up and
down at 1 cycle/sec.

Ping pong balls are not conductors or constructed of diamagnetic materials.

>Which has this levitation effect

Gravity does not have a repulsive force that can be observed, therefore
there can be no levitation effects that can be observed. Please do not bring
up dark matter.

> connection

> respect to
> tank circuits and oscillation?

Tank circuits cannot cause repulsive gravitational forces.

We cannot construct gravity amplifiers.

Such is the mythology of Area 51.

I went along to a couple of meetings many years ago. Full of under achievers with high IQ's complaining how they weren't being recognised or credited in their exams/career/promotion ladder/etc.

You can coast along with a high enough IQ without having to work too hard, but it takes hard work and dedication to achieve anything worthwhile. The top people anywhere in the world are not the smartest, but they learned to use what they have to the maximum and put the hours in. If you expect a high IQ to grant you a short cut to the top, it won't and there are a whole lot of only slightly less intelligent people who know just enough and have a vested interest to stop you from getting there.

Mensa is merely a self congratulatory society for smart people who lack the drive to succeed. But don't let that stop you from joining so long as all you expect is the chance of some (reasonably) intelligent conversation at social functions.

Well it didn't match up to my standards (or the intelligence that is displayed on r.r.a.a.) so I didn't bother renewing my subscription when it expired.

Cheers all,

Mike GOULI

Hi Mike
What you say is very true, but, Art is not looking for
confirmation
he has already stated that he is not going to hand his findings to
this group on a plate.
What he is trying to do is guide others to find for themselves what
he already knows.

Derek

>
> Perhaps there is just no reason why the "phase shifts" should add
> to 90. That would make the problem go away.

That is just a mis-statement of the case. You just have to keep track of the
money:

When the men come in, they have $30

When they have paid for their rooms, they have $0 and the hotel has $30

When the bellboy takes the money to give back to them, they have $0, the bellboy has $5 and the hotel has $25

When the bellboy gives them the money back, they have $3, the bellboy has $2, the hotel has $25

The fallacy here is to think you can "add" the bellboy's $2 to the $27 they have paid for the room. It's already part of that $27, as it's $25+$2

David
Go to your books and read the basics on Gauss with respect
to a arbitary field.
I am beginning to belief that you have lost everything
that you learned in college. Have you had a heart attack or
a stroke sometime in the past which would explane that?
Art

The solution to the tilt angle is follows:

Assume the earth is curved.

Observe that the radio horizon is actually 15 degrees below the visible
horizon.

Now assume the Earth is flat.

In that case, you must tilt the propagation angle 15 degrees from horizontal
for maximum propagation.

Impossible to do that if they don't understand the basics of physics!
I was hoping an inquisitive educated person would come along and read
but we rarely have such a visitor as the groups reputation procedes
us.
I will put the subject away for a more suitable time where it can be
properly debated.On top of that none are able to operate a antenna
computor program or even want to which bring things to a dead end.
Enuf for now. For the present I will call it a day and move on.
Art

In my attempts to engage art, he's rebuffed my knowledge (more like lack of it) I'm supposed to come back after I learn more. But learn what? Theory that he declares is incorrect, or his theories which he won't serve up? The others will share with me.

I'm just not much of a fan of faith based engineering! ;^)

To convince others of a new and radical departure from what exists and what apparently works, one nust offer good proofs. The old "extraordinary claims require extraordinary proof" chestnut applies. And especially for people such as Roy, who has often been decried by Art. He is under no obligation to prove Art either right or wrong.

I explained it already. The current maximum in a loading
coil is caused by the magnetic flux linkage between the
adjacent coils. It is the same thing that approximately
doubles the velocity factor of the coil over what it
would be if the all the current followed the wire.

Intelligence is like talent. It is a gift.

What you do with it is what is important. Just because you have one or the other is almost irrelevant if you don't have the other tools needed to be sucessful.

Unfortunately, autistic people can, quite frequently, score high on IQ tests--however, it is obvious this "gray matter" is not what one is looking for (well, sometimes NOT all that obvious.)

However, without the proper gray matter--you can grunt all you want with little progress ...

He wants RRAA validation.. :/

> he has already stated that he is not going to hand his findings to
> this group on a plate.

After the 3496 miles of fairly incoherant jibber jabber I've read of
his,
I'm so confused I don't even know what his "findings" would be. :/
They seem to change from week to week anyway.
He was touting maximum horizontal polarization, but in his latest
post claims vertical is the only way to fly.
He'll claim all elements are fed in phase, but then claim only
one element is fed. He claims that if you are not using a full
wavelength element, you are not living, and just don't get it.
Like the old codger with too many dogs in "Moonstruck", I'm confused..
:/
But if you talk to Art, he is the only sane one in the group, and
we are all the confused ones.
Everyone, including the electronic engineers of the group are all
living in the past, brain dead, or just don't get it.
But Art, the mechanical engineer who is dabbling in an area
he is not really trained for, has all the answers, and is ready
to rewrite all the books.
I'm not going to hold my breath waiting for this vast overhaul
of gaussian equalibriated gobblygook into the future textbooks..
I have no problem at all with anyone trying new ideas, but
they should test and prove them before proclaiming as fact,
rather than the other way around.
Art talks a great storm, but I see little indication he actually
builds and tests what he is talking about.
As I've muttered before, that is no way to live.
Want to know what the real deal is?
I can tell you.
Delusions of grandeur brought on by his various computer
modeling programs he tinkers with.
He stumbles into something he finds interesting when
modeling, and then he tries to use gaussian bafflegab to
explain it as some new invention. I'm serious.

I can see no other explanation for this behavior.

> What he is trying to do is guide others to find for themselves what
> he already knows.

How does he know I want to find what he already thinks he knows?
He seems to want to gravitate towards small overly lossy antennas
designed using fairly perverted theories of operation.
I'll have none of that mess around this household.
I want big manly ultra efficient antennas that brown the food in all
directions at once. :)
MK

Considering that our president has the I.Q. of the slowest learner in the slow learners class at the local obedience school, it's obvious it doesn't take intelligence to get ahead in life. Truman and Nixon weren't much better. From what I've read, intelligence tests were invented in France to identify students with learning problems in order to give them additional attention. When the test got to the U.S. it was immediately used as a way to stratify society. One of the chief fellows behind the American effort was a Stanford academic named Lewis Madison Terman, who, of course, was awesomely intelligent by definition.

No, but I agree with myself that whatever voltage is applied to
the input will be canceled by all the reflections in the circuit
adding up to a voltage at said input that will cancel the input voltage.
It's like finding the zeros of a network equation.

I'd be interested in hearing why people bother to join MENSA and why they'd attend meetings. Where's the fulfillment in standing around in a room full of folks congratulating each other on how smart they are?

It isn't the numbers in your IQ which are important, Cecil, it is what you do with 'em.

I think I see why it no longer surprizes me after going through the smith
chart.
The 100 ohm line (10 degrees) is open. The 600 ohm line has a load impedance
of -j567 ohms, it is not open. The fact that it is terminated with an
impedance (the 100 ohm line) adds degrees on the chart. We should expect the
reactance of the 100 ohm line to add phase angle at the termination similar
to a "discreet component". Hope this makes sense; the smith chart makes it
very clear.

WOW, deja vu, I have seen parents beat down children because the lesser intellect-ed parent feels threatened, lessened, unimportant (and usually, rightly so)--this is a sorry thing to watch in a workplace. To watch it occur in a family is nothing less than utterly disgusting.

So much opposed to the wholesome and functional family which devotes all to the importance of the individual and encouragement of the youngsters to out achieve the parents ...

Where was/is child protective services when the kids need 'em?

If one is a control freak, keeping silent on these affairs allows one to keep their illness hidden ... the terms you use are a dead give away.

Wow, "John", you managed to read in some things never written by me. I wrote nothing of parents being threatened, lessened or feeling unimportant. I've never watched any parents exhibiting such practices in their or a child's workplace either.

The curse is that the parents often place unreasonable expectations for success on a child marked as gifted. You must feel like a fool right about now.

> So much opposed to the wholesome and functional family which devotes all

Well, you didn't answer them all did you? And you didn't really have anything to show short of those answers until I asked for them, did you? And you certainly don't have a page of published RESULTs such as Tom has where the settings and readings are all readily visible and available, do you?

Of course this laborious, tedious, and painstaking. This is called the work of science and engineering - or you could just go back to mooching for validation, the correspondence you commit to that in a hour far exceeds responding to these few questions over several days.

So, what voltage magnitudes were presented to the inputs of your scope? or should I consider your silence to a rather ordinary question as you having hit the limit of your technical depth?

Did you take the input to Channel 1 from this autotransformer?

Fine. I've changed your sentence to read:

"Means it is acknowledgment of the worth of transparent, practices and
knowledge ..."

> you neighbors, you family members
> know--...

Me neighbors and me family members will think it reads awfully funny.

> ...attend a self-help group ... it may help others around you.

No thanks, John. If you're an example of what self-help groups have
done, I believe I'll give it a pass.

If I had to venture a guess, I'd guess you're the wrong guy to explain
what goes on at a MENSA meeting.

Posting-Frequency: posted monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been
recently revived by an active moderation team. We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/ ):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

We are willing to provide any technical support necessary to get this
article updated and automatically posted again at a regular interval.
This would include establishing contact with the original maintainer for
any necessary permissions. We would prefer to seek a new, dedicated
maintainer at this time, rather than start auto-posting the original
article ourselves.

2682. Quad loop supported by single tower - NEC2 modeling question

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-07 07:17:22 UTC
From: mcclements@gmail.com
Message-ID: <9fd877df-a59f-444b-afe7-bf8953144946@d4g2000prg.googlegroups.com>
Source record: 32139

Hi,

I am modeling a vertically oriented, vertically polarized loop for 160 meters. The loop will be supported at the top of a 130 foot tall tower with a 6 foot standoff arm. The Bottom of the loop will be 10 feet from the ground. I was modeling the exact physical layout of the loop with NEC2 without considering the tower structure in the model at all.

The tower is Rohn 45G with non-conductive guy wires. Not wanting to duplicate the exact tower model in NEC2 (by hand), I substituted in essentially a wire with a diameter of 1 foot, using steel for the conductor. I am modeling the antenna over 'real ground'. Putting in this wire next to the antenna had a pretty big impact on the resonance frequency that NEC2 reported. The pattern is slightly altered as well.

My question is, 1) Am I taking too much of a shortcut to use a single wire to represent the tower? I just wanted a *rough* idea if this tower length (1/4 wavelength on 160) was going to have some impact on the pattern in the real world. Resonance frequency shifted down in frequency 35Khz in my model.

I've modeled and built loops that I've installed between trees and the results have matched NEC2 very well, but I don't know what to make of the support steel tower in this case - am I overstating its effect the way I modeled it?

>>

Every author has a problem in drawing those diagrams, because we are trying to draw too many things at the same time: physical height, electrical height, loading coils, current distributions and voltage distributions. It doesn't matter which viewpoint we are trying to illustrate, it is still impossible to draw *all* of those things truthfully to scale on the same diagram.

When comparing the full quarter-wave against the mobile whip, we have to choose: do we draw the two antennas to true physical scale; or do we use an 'electrical' scale of 0 to 90deg? Whichever one we choose, the scale for the other on becomes grossly distorted, and this is what leads to confusion.

Every author has trouble with this. Illustrations by different authors attempt to square the circle in different ways, but none of them ever can succeed because it fundamentally cannot be done.

ARRL publications are no exception, and a further complication is that the handbook compilations tend to re-use illustrations from individual articles by different authors. So please don't read too much into the mixture of drawing styles - the reasons are often more historical than technical.

>
>It has been changed. There is no longer any discussion of "degrees",
>only "current".

Well, not quite. The 4th edition does use degrees for the electrical lengths of the plain unloaded sections (which is valid from everyone's point of view); but it no longer implies that the loading coil "replaces" any number of degrees.

I don't know the detailed history behind that change, but I do know one thing: ON4UN is not a man to be swayed by "political" influence. The change in the 4th edition would be because he was challenged to look again at the *technical* issues, and then he made up his own mind.

> So are we agreed that a 43.4 degree stub terminated in
> 0-j567 ohms impedance is electrically 1/4WL, i.e. 90
> degrees long?

There are many ways to get the 0 input impedance:
- 43.4 degrees of 600 ohm line terminated in a lumped 0-j567 impedance
(assuming I recall the problem corrrectly and you did the math
correctly)
- 43.4 degrees of 600 ohm line followed by 46.6 degrees of 600 ohm
line, open at the end
- 43.4 degrees of 600 ohm line followed by 10 degrees (IIRC) of 100
ohm line, open at the end
- a short
- 180 degrees of any impedance line shorted at the end
- and many, many more

Are you claiming that all of these are electrically 1/4WL ?
Even the 180 degree line? And the short? Seems like a stretch.

And when looked at in detail (think time domain for moment), they each
behave quite differently.

You have done this before; postulating
explanations that only work in the complexity
of the "real" world, but fail when presented with
the simplicity of ideal test cases.
Then, when the explanations fail on the simple
cases, claiming these cases are not of interest
because the real world is more complex.

It won't fly. Good explanations also work when
presented with test cases from the simpler
world of ideal components.

Gauss's law is a law of 'electrostatics' as art so frequently states.
STATICS is static, ie NO current which would be implied by adding a time
component to the charge or field predicted by Gauss's law. If you have a
time variable charge you have a current, if you have a current then you
have to include the magnetic fields, and the curl of the electric field, and
hence end up needing all 4 of Maxwell's equations to define the complete
solution. So yes, i say you can not add time variations to Gauss's law as
it stands alone and completely describe the solution to the fields produced.

i.e. simple proof. define any shape surface with no charge enclosed in it.
by Gauss's law the net field through that surface must be zero. you can
have charges sitting just outside of it, lets say a single electron is just
outside of one side of the surface. if you integrate the field from that
one electron it goes in one side of the surface and out the other and all
still adds up to zero net field as require by Gauss's law. now for the hard
part.... move the charge a little bit closer to the surface without going
through it. we must all agree that while you are moving it the electric
field strength through the surface closest to the charge is increasing, so
in order for the total flux through the surface to remain zero the flux
moving out on the other side must also increase. BUT because of the effects
of the other 3 Maxwell equations that limit the speed of propagation of that
field to c it can't happen instantaneously. so for some period of time the
net flux through the surface is not zero as would be require by Gauss alone.
reductio ad absurdum, QED, take your new theory and....

---43.4 deg 600 ohm line---+---10 deg 100 ohm line---open

The Smith Chart does make it clear what is happening.
Here is the math to go with it. The impedance at the
junction of the two lines is:

-j100*tan(90-10) = -j100*tan(80) = -j567 ohms
-j600*tan(43.4) = -j600*tan(43.4) = -j567 ohms

The phase shift at the junction of the two lines is:
80-43.4 = 36.6 degrees

Time permitting, I will work up the phasor diagrams of
the component voltages (or currents) at the junction
where rho = (600-100)/(600+100) = 0.7143

> where rho = (600-100)/(600+100) = 0.7143

If the 100 ohm line was only 5 degrees long, how
long would the 600 ohm line have to be to obtain
0 ohms at the input?

Would the phase shift at the junction still be
36.6 degrees?

> Do you want to work that out mathematically?

For the stub to be electrically 1/4WL, the following
must hold where L1 and L2 are in degrees.

-jZ01*tan(L1) = -jZ02*cot(L2) = -jZ02*tan(90-L2)

-j600*tan(43.4) = -j100*cot(10) = -j567 ohms at the junction

When L1 = L2, the stub is half Z01 and half Z02.
Such a stub is very close to 1/2 the physical length
of a single-Z0 stub when Z01/Z02 = 6.

> "replaces" any number of degrees.

"Replace" seems to mean different things to different
people so it is not a good word to use without a stated
definition. It would probably be better to say the loading
coil "occupies" a certain number of degrees in a loaded
antenna.

The number of degrees occupied by the coil varies but it
is in the tens of degrees for a 75m mobile loading coil.
Here is an EXCEL file that computes the Z0 and VF of a
loading coil assuming it meets the "less than 1" test
included in the computation. Of course, the results
are only approximate since some secondary effects, such
as wire diameter, are ignored.

http://www.w5dxp.com/CoilZ0VF.xls

The VF of a 75m Texas Bugcatcher coil is ~0.02 at 4 MHz.
Since it is ~7 inches long, it occupies ~43 degrees of
antenna. The stinger occupies ~10 degrees so the coil
indeed does not "replace" 80 degrees of antenna. It
occupies 43 degrees of the antenna. The rest of the
necessary phase shift, 90-43-10 = 37 degrees, occurs at
the coil to stinger impedance discontinuity where the
Z0 of the coil is ~4000 ohms and the Z0 of the stinger
is ~400 ohms. A 10/1 ratio of Z0s causes a considerable
phase shift in the traveling waves, not in the standing-
waves.

One side of the argument recognizes only the phase shift
through the coil. The other side of the argument recognizes
only the phase shift at the top of the coil. Both sides
are partially right and partially wrong. Interestingly,
the truth lies just about half way in between the two
rail arguments. About half of the "missing degrees" are
contributed by the part of the antenna *occupied* by the
coil while the rest is contributed by the impedance
discontinuity between the coil and the stinger.

If he changed his mind based on experiments using standing-
wave current measurements, he is still wrong. I have tried
to contact him using his ARRL email address, but got no
reply.

If you calculate the complex rho and calculate the phase
shift provided by a -j567 impedance, you will agree with
my statement above.

> Are you claiming that all of these are electrically 1/4WL ?

Of course not!!!! I numbered your examples above. Examples
1-3 are electrically 1/4WL long. Example 4 is 0 WL long.
Example 5 is 1/2WL long.

All my remarks apply only to stubs and antennas that are
electrically 1/4WL long. My remarks do NOT apply to any
stub or antenna that is not electrically 1/4WL long. An
ideal open stub that is 3/4WL long has the same impedance
as a 1/4WL stub but is it obviously not 1/4WL long.

For Pete's sake, Keith, Ohm's law doesn't even
work when R=0.

> Then, when the explanations fail on the simple
> cases, claiming these cases are not of interest
> because the real world is more complex.

I define the boundary conditions within which my
ideas work. Whether they work outside those defined
conditions is irrelevant. I believe they do work
for ideal conditions, but I don't have the need
to prove a "theory of everything".

Every model that we use has flaws. Asking me to
come up with a flawless "theory of everything"
model is an obvious, ridiculous diversion but
you already know that.

-jcot(5) = -j11.43 normalized to Z0=100 ohms

-j100(11.43) = -j1143 ohms at the junction

-j1143/600 = -j1.905 normalized to Z0=600 ohms

arctan(1.905) = 62.3 degrees of Z0=600 ohm line

> Would the phase shift at the junction still be
> 36.6 degrees?

The new phase shift would be 90-5-62.3 = 22.7 deg.

62.3 + 5 + 22.7 = 90 degrees

This example would correspond to a larger coil and
a shorter stinger in a loaded mobile antenna.

Source record: 32060

Well, I did mention in another thread that Cecil had already passed
the milepost indicating the point of no return:

On Tue, 04 Dec 2007 19:16:01 GMT, Cecil Moore <nospam@w5dxp.com>
wrote:
> I also measured ~12-13 ns delay
>through 50 turns of the same coil stock that Tom
>was using when he measured a 3 ns delay through
>a 100 turn coil.

The "results" (not corrected for errors as all of Cecil's arguments
drawn from reality are cast as perfections - a clash that always
amuses me) at this point Cecil confirmed/validated Tom's screen shot.

How? Tom's instrument is built to compensate for two channel
measurement errors, an ordinary scope is not. There are many issues
to resolve when using an ordinary scope before results (then corrected
for error) can be used in comparison.

Why? The error is an inherent disparity in using two channels, and
their different rise times. It shouldn't take a degree in engineering
(many who own scopes can confirm this) to realize that an identical
event, traveling through the parallel chain of amplifiers eventually
driving the deflection of the parallel traces; each of those in the
pair will arrive at a different time.

What? It only remains to resolve which chain presents more (or less)
rise time. It is not uncommon to find in the extreme (exactly where
Cecil's measurement resides) that rise time differentials can easily
equal the time delay measurement cited above in the quote, but for
Leader O'Scopes, a calibrated model can exhibit up to 17.5nS rise
time.

Remove that differential, and the error corrected delay collapses
towards Tom's results! If we consider the span of all error easily
washes over the resolution of the measurement, then Cecil's particular
test was a non-starter as it is arguable that it was ever performed.

Cecil could yet pull some of this error out of the mud, but his memory
is foggy, he can't find things, problems beset him, poor eyesight may
have disturbed what he reported (transcription error), his
instrumentation isn't calibrated, he even admits to the possibility of
spelling errors (communication failures in this forum seem to be
embraced as a mark of populist heroism in the face of sterile
engineering), and on and on until:

SUDDENLY a new fact arises that completely
vindicates Cecil! A new vigor rises, and there are
more than 20 answers to supply!
Memory suddenly clears,
the lost notebooks are found,
problems vanish,
eyesight is restored to 20/20....
well, let's say that drama takes center stage
as the magician's cape opening reveals the rabbit.

There are other errors to answer for, this one was simply the first to engage Cecil in his stumbling attempt cursing the pebbles in the path as boulders. The absolute best outcome Cecil could reasonably expect to show is the standard RL of an ordinary coil, and Corum would have to wait for a future validation. Of course, this future occasion would demand far better controls, tighter readings, better reporting; and, of course, this verges on the dictates of engineering.

The cursing will, no doubt, follow. :-)

This from the person who asserted that the reflections
from a non-reflective thin-film coating are brighter
than the surface of the sun. Richard will twist facts
until there is zero resemblance to reality.

Richard, I have no idea what your ulterior motive is
but is it certainly not leaning toward technical facts.

If you don't like my measurements, then please explain
the phase shift through the EZNEC coil model at:

http://www.w5dxp.com/coil512.ez

Almost anyone is capable of creating a forward traveling-
wave through a real-world coil on the bench, as I did, and
measuring the phase shift. Have you done that? Obviously
not, since to do so would force you to side with technical
facts, and not with the old wives' tale you are promoting.

Use a TDR to measure the delay through a 75m bugcatcher
coil and get back to us with the results.

And for that, as well as the forecast shortage of substantive data, it
amounts to just a quick peek. When any data is offered and examined,
the thread quickly ends as it should. I count myself lucky to have
played to Cecil's ego long enough to tease out the "facts."

Ego certainly overwhelmed the other thread which blossomed into the
MENSA celebrity network. That group must have restricted chapters
that act as guard channels where the wannabees are collected for later
culling.

Roy, I more than welcome anyone, including you, looking
behind the curtain for the technical truth. Unfortunately,
you have ploinked my postings and emails and refuse to
look at the considerable evidence that even EZNEC supports.

http://www.w5dxp.com/coil512.ez

Anyone who wants to take the time can download this file
and see how wrong you and others really are. When you
received that file in your email, you threatened to take
EZNEC support away from me and refund my money. Selecting
"Load Dat" clearly shows the phase shift through the coil.

You earlier admitted that EZNEC reports almost no phase
shift in the current from end to end in a 1/2WL dipole
so you should be perfectly aware that same current cannot
be used to measure the delay through a mobile loading coil.

Using political power to try to hide technical facts is not
an ethical thing to do. This time, some are looking behind
the curtain and understanding the physics involved.

The smith chart shows this well. If I go up only 5 degrees on the
outer circle of open-end (infinite impedance on the 100 ohm line),
lower values of electrical angle corresponds to higher reactance, in
this case -j1143 for the 5 degree line instead of -j567 for the 10
degree line at the junction. The new phase shift at the junction
should be, and is, now lower since the 100 ohm line has a higher
capacitive reactance at the junction. As the 100 ohm line is shortened
to 0 degrees, we have a 600 ohm transmission line that is open and now
the 600 ohm line must be lengthened to the full 90 degrees for 1/4W.
This would correspond to a coil with no stinger.

So sometimes a 600 to 100 ohm discontinuity
produces a 36.6 degree phase shift and sometimes
it produces a 22.7 degree phase shift (and probably
any value in between).

I suggest that "work[ing] up the phasor diagrams of
the component voltages (or currents) at the junction
where rho = (600-100)/(600+100) = 0.7143" will
not be useful for predicting the phase shift.

A rather large red herring. Ideal components are
the topic, and we mostly use ideal wire with R=0
without difficulty.

> > Then, when the explanations fail on the simple

Sounds good, but mostly you do not examine
ideal conditions because they tend to show that
the models fail. With non-ideal conditions, the
discussion is easy to drive far from the target
and prevent resolution of whether the model
works.

My postulate is that Newton was wrong: moving objects come to a rest without any external applied force. Every observation made supports this. There's no need to consider what happens in a frictionless environment, since such a thing doesn't exist.

That's right, depending on the electrical (and physical) length of the 100 ohm line, it will have different values of reactance as seen by the 600 ohm line, therefore different phase shifts, all the way to zero when the length of the 100 ohm line is 0 degrees and the reactance is infinite (the 600 ohm line sees an open circuit). Say at 0+ degrees, -jX(C) = 1000000000; this is where you see it headed when you look at the smith chart.

At zero degrees of 100 ohm line, you have 90-0-90 = 0 degrees at the discontinuity.

> stub or antenna that is not electrically 1/4WL long. An
> ideal open stub that is 3/4WL long has the same impedance
> as a 1/4WL stub but is it obviously not 1/4WL long.

Your original claim was that 43.4 degrees of 600 ohm
line terminated with 0-j567 was electricall 90 degrees long.
You made no reference to how the 0-j567 was obtained.

You have said that 1, 2 and 3 from above are electically
90 degrees.

How about:
(6) 43.4 degrees of 600 ohm line, 180 degrees of arbitrary
line terminated in a lump of 0-j567. This is just another

way of placing 0-j567 at the end of the 43.4 degrees of 600 ohm line.

And (5), if we use 600 ohm line is also 43.4 degrees of 600 ohm line terminated with 0-j567, this being obtained with 136.6 degrees of 600 ohm line that is short circuited.

So while I can accept your statement , "My remarks do NOT apply to any stub or antenna that is not electrically 1/4WL long.", I am having great difficulty coming up for a rule so that I will know when your remarks apply.

Can you provide a rule for discerning when a stub or antenna is electrically 1/4WL long?

You've done the right thing. The tower features are a tiny fraction of a wavelength, so the single wire substitution is fine.

To improve the accuracy of the model, use the equivalent radius of 0.421 foot for a triangular tower with one foot sides. This will likely make a noticeable difference only if the tower is somewhere in the vicinity of self resonance.

This represents the expected cries of anguish more than correspondence
to the immediate topic with N greater than the 20th question where
formerly Cecil was loath to proceed beyond...

As observed earlier, threads driven by data rarely present the
entertainment that enthralls many to submit upwards to 500 postings.

I see no further data regarding the topic is forthcoming, an expected
outcome, but certainly not Cecil's best option. However, Cecil is the
only one that can fill in the blanks of a measurement that appears
never to have been made. There appear to have been no witnesses that
can independantly supply that data either. As such, nothing is left
to be said that negates my conclusions set forth in this thread as
were drawn from the only data available.

Of course, Cecil could impeach his own data. :-)

Regarding Dr Davis's mathematics. Richard stated the other week that
of course it is correct. If you feel that he also is in error
why not contact him? I am sure he can comminicate why much more
clearer than I
You are now left with the troll KB9... in your efforts to argue that
point
I personaly recognise that I will never be able your mental state up
to par
with respect to Gauss or your troubles with the word equilibrium.
There is hope for you however , Roy now states that NEWTON of all
people is wrong so you do have company in a strange way.
But then it may be company that you wouldn't wish for!
He personally attacked Cecil some timeago. Last week his personal
attack on me
was really venomous so you certainly should not disagree with him in
any way.
I think you would be better off asking guidance from Richard, why not
try it?
Art

Yes, of course - nobody said the phase shift wasn't
a variable. Why would you expect it to be a constant?
It is a variable that depends upon the phase of the
component forward and reflected waves.

> I suggest that "work[ing] up the phasor diagrams of

It will be useful for reporting that particular phase
shift. If other conditions change, that phase shift
will change. What is unexpected about that?

We'll never know to what you refer, "John". You snipped it.

Look, you're already using a pseudonym, why not just admit that you're
that kid you mentioned?

If you're accusing me of talking to myself, walk through the scenario.
You made a newsgroup response to one of my posts. I responded to you.
You responded to me. I responded to you. It is apparent that I'm not
talking to myself.

Dave K8MN

Of course, if you add 180 degrees you have added 180
degrees to whatever existed before. Do you disagree?

> Can you provide a rule for discerning when a stub or
> antenna is electrically 1/4WL long?

Of course! When the reflected wave undergoes a phase
shift of 180 degrees in its round trip to the end of
the stub and back, the stub is electrically 1/4WL long.
How can you disagree with that?

Yes, you did say that, but it isn't apparent to me that the two statements are necessarily mutually exclusive. To me those things are all interdependent. Insofar as constructive interference is caused by reflections from discontinuities and not the other way around, then yes. But the current maximum is simply an area of constructive interference. It is the profile of a standing wave in 2 dimensions caused by the superposition of forward and reflected waves. The phase and amplitude of the forward and reflected waves are of course determined by the nature of the line, and those parameters determine the profile of the standing wave.

> It is the same thing that approximately

I think current is required to follow the wire in any case. :-)

This is a request to any readers of r.r.a.a who are
capable of performing the experiment that I performed.

Use the EXCEL file at:

http://www.w5dxp.com/CoilZ0VF.xls

to estimate the Z0 of your test coil. If the test entry
is greater than 1.0, try another coil.

Here is the test setup using a 75m Texas Bugcatcher coil:

http://www.w5dxp.com/coiltest.gif

Using a 50 ohm source, install an autotransformer to
achieve the Z0 of the test coil on its output.

Load the test coil with a non-inductive resistance
equal to its Z0 value.

This will ensure that most of the current flowing
through the coil is traveling-wave current and not
standing-wave current.

Report the phase shift through the test coil.

This is an easy test to do. Of course, none of the
resident gurus will run the test or report the results
if they do run the test because it will prove their
old wives' tale to be wrong.

The distance between current anti-nodes is 180 degrees.
All the lack of apparentness in the world will not
change that fact of physics.

Wrong.. When you are beyond the confines of all gravitational fields
and in a state of equilibrium then there can not be friction.
Somebody somewhere has obviously postulated that gravitational
forces are every where which puts science back in the stone
ages.
Sure messes up Gauss and quite a few others. In fact the law
of
statics is based on gravitational field which extends to what
Gauss called the limits of gravitational effects.
Quite a few other laws are based on similar logic

That has got to be the worst logic I have EVER heard and flies in the face of common sense to be unspeakable--Roys' comment.

An object in motion, with NO external forces HAS to continue to move with exactly the same stored energy as it began with, even a trillion years later ...

Logic asks: Where would the stored energy go? Imparted to nothing? Just disappears--breaking all the laws dealing with the conservation of energy also?

Art, give up, we are in the twilight zone, look for an exit!

However, an ABSOLUTE frictionless environment may be quite difficult to come up with ...

JS

Hi Art,

It was some schlemiel called Isaac Newton.

He offered a very simple equation you probably are not familiar with:
G times the Mass of Body A time the Mass of Body B
divided by
distance between them squared

This English clown's theory was put into a cocked hat by Einstein - so
you two have something in common!

Hmmm, the 20mg Hydrocodone has more of a "kick" than I realize.

Regards,
JS

I did not know that equation. Einstein said a lot of things and
was often proved in error. Did he mention equilibrium or the
other laws like:
Every action has an equal and opposite reaction? For that matter
how many laws of Newton did he put down?
Any idea where I can read up on that and how he arrived at that
conclusion? Seems odd that we have so many gravity centers in this
universe and a neutral point never occurs.....anywhere.
Some of those stationary things in the sky must be holding on to a
piece of string tied to the moon
No. I do not have any books on Einstein but do have Planck and
I don't recall him mentioning that.Is it just called Einsteins Law
of ???????
Art
Oh, and another thing why are you injecting the word "clown"?
Are you reverting to your old tricks or did you just slip up?

So this meets the criteria you originally proposed and
is an example of 90 degree electical length?

So (4), a short, meets this criteria. It did not have to go
far down the stub, but it did arrive back with a 180 degree
phase change. But previously, you did not include (4).

Is it now in the list?

You implied that you were going to compute it
using just rho, which would mean it would be
constant for any pair of impedances.

With more inputs, it might be possible to
compute a number that, when added to the
actual electrical lengths of the lines, will
result in 90 degrees. I expect the algorithm
to be fairly complicated.

Of course, one can always just say it is equal
to 90 minus the sum of the electrical lengths
of the lines, though if there were two or more
impedance discontinuities, it might be difficult
to apportion the difference between them.

I await the algorithm.

The best example was when you refused to discuss
the reflections at the output of an amplifier with a
well defined output impedance because a typical
amateur transmitter does not have a well defined
output impedance.

The discussion was going to demolish the idea of
complete re-reflection at the output of a transmitter
but stalled because you refused to use the simple
case to examine the issue. Using the more
complicated scenario of a real transmitter it was
much easier to obfuscate with the result that the
discussion went nowhere.

Which was sad because there was much
opportunity for learning there.

Caution; those numbers assume that for each variable 100 ohm length, you
have defined by measurement that the system had a 90 degree phase shift.

Don't be silly. 180 degrees plus any positive angle
is more than 180 degrees.

The context was mobile loaded antennas shorter than
a physical 1/4WL.

No, I did not. Rho can be constant but the phase
angle of the incident voltage changes with
position. Therefore, the phase angle of the
reflected voltage changes with position.

This subject is already covered in my energy
analysis article at:

Not so. A simple example is called the "Trojan points."

>Some of those stationary things in the sky must be holding on to a

Well, given the moon moves, the string must move whatever is tied to
it. In short, there is nothing stationary anywhere.

Actually, you can store energy in an electrical field easily enough; ask any capacitor. And energy has a mass equivalent. It may not be much, but it isn't zero. This probably isn't what Art means, though. If you thought about his post deeply enough, and in just the right way, you'd see what he's getting at. Smart ass questions aren't helpful. Not that I'm agreeing with Art. I'm not. But if you want to understand, as opposed to just being sarcastic, you'll have to train your mind to operate the way his does. Cecil, on the other hand, wants to argue, so his posts aren't as much fun, but he does write some entertaining things on occasion, and his theories are tolerable enough as long as you realize they're all quite wrong.

This isn't a diversion: it's the core of the whole dispute.

These days, mathematical models are the normal, everyday way that engineers go about their business. A bedrock principle is that if a model is going to be usable and trustworthy, it MUST join up correctly with existing knowledge. Your model can be as elaborate as you like, but it always has to prove itself against the simple cases that we already know about.

Anyone with experience knows that these "simple" reality tests are the most often the hardest for an elaborate model to pass... but that doesn't excuse them from the test. If a model cannot handle the simple situations that we do understand, we can never trust it in more complex situations.

Ohm's law is a perfect example of a model that works. The whole point is that Ohms' law IS a good model of reality for a very wide range of situations, including the simple but extreme case where R equals exactly zero. It's absurd to suggest that there's a glitch - it simply means that V would be exactly zero too.

Likewise there are no glitches in the standard circuit models for inductance and capacitance. They work just fine, for all cases where the dimensions of the circuit are very small with respect to the wavelength, so that distributed effects and radiation are negligible. Where those assumptions are no longer accurate, we can extend the simple model to include some corrections. But the most important point is, we always know that we're building up from a solid foundation.

That is also the sensible way to think about loaded antennas. Calculate it the simple way first, assuming lumped inductive loading, and then apply corrections as necessary. As I've said before, this simple, solid method is the one that works. It can take you straight to a workable prototype, which can be quickly adjusted to frequency. Countless authors have demonstrated how to do this, and anyone can download G4FGQ's MIDLOAD program to do the same.

While other people choose to build on those solid foundations, Cecil insists that simple routine reality tests are a "diversion". He prefers to keep his floating castles well clear of such hard rocks.

Hmmmm. So you are no longer in agreement with your
original question:
"So are we agreed that a 43.4 degree stub terminated
in 0-j567 ohms impedance is electrically 1/4WL, i.e.
90 degrees long?"

This is good. You can now understand why some were
not quick to jump to agreement.

The concept of electrical/physical degrees is an
occasionally useful way to think about delay on
a transmission line that is used in a single frequency
environment. It even helps understand stubs where
the reflection arrives back with some phase shift
from the original. But extending the concept to lumped
circuits or expecting to find 90 degrees when different
impedances are involved has little value. It leads
to worthless questions like "where did the missing
degrees go?"

This is much like ascribing excessive reality to
"reflected power" which leads to worthless questions
like "where did the reflected power go?".

Or asking "where is the missing dollar?'. The flawed
underpinnings lead to worthless questions. Well maybe
not worthless, like the hotel puzzle, they test the
ability of the answerer to detect flawed assumptions.

The point is that IT OBVIOUSLY DOESN'T WORK, Ian, for
the delay through a loading coil. If it worked, W8JI
would not have gotten a 3 ns delay through a 2" dia,
100 TPI, 10" long loading coil. If his test setup
looked like mine, he would have measured a valid
delay around 25 ns.

http://www.w5dxp.com/coiltest.gif

Ian, are you afraid to run that test for yourself?

> Cecil
> insists that simple routine reality tests are a "diversion".

Please don't twist my words. I insist that simple routine
UNreality tests are a diversion. But, my personal opinion
doesn't change anything. The model that I am using works. The
model that W8JI is using doesn't work.

Please take a look at: http://www.w5dxp.com/coil512.ez
and tell me why EZNEC disagrees with W8JI's model.

Now I understand your confusion. I was talking about
a -j567 ohm *capacitor*, not a virtual impedance.

I was, of course, using the "impedor" definition of
impedance but since that confused you, let me restate
the question:

"So are we agree that a 43.4 degree stub terminated in
a -j567 ohm impedor is electrically 1/4WL, i.e. 90
degrees long?"

This was the original meaning of the question. I'm sorry
that you took it the wrong way and wasted so many postings
on such a trivial misunderstanding.

> It leads
> to worthless questions like "where did the missing
> degrees go?"

Click on "Load Dat" in the EZNEC model below. There are
no missing degrees. All necessary degrees are present
and accounted for. But you will never see them if you
are trying to use standing-wave current to see them.

http://www.w5dxp.com/coil512.ez

> This is much like ascribing excessive reality to
> "reflected power" which leads to worthless questions
> like "where did the reflected power go?".

Since energy must be conserved, the proper question
is: "Where did the reflected wave *energy* go?" Do
you even know the answer? The answer is that there
is exactly the amount of energy existing in a transmission
line to support the forward wave and the reflected wave.

Conceptually, I know what has to happen based on the
principle of conservation of energy, i.e. all energy
is conserved. If the reflected wave energy is not
entering the source, it is being reflected at the
source. That is all I was saying during those posts.

2791. How to match 190 +j140 to a 50 ohm source?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-08 14:58:33 UTC
From: s.g.hatch@gmail.com
Message-ID: <a1979804-1adb-46cc-bc57-87e8b4378cd6@s8g2000prg.googlegroups.com>
Source record: 31948

that about sums it up.

stub matching looks attractive, but how do I actually build one of
these suckers? Do I have to carve out a piece of coax and then fit
another one into it, if that makes sense? Won't that be nearly
impossible to solder?

physically, it would be easier to make a stub section with sections of
single wire line, but I don't know how to find Z0 of my 14 gauge wire?

Is stub matching not the answer?

The antenna is designed for about 450 Mhz, if that helps anyone.

Thanks for your help.

Should be easy enough to check the claims. If as Art suggests there is a constant interchange of particles in the surface element of a radiator, then some detectable physical changes should take place. Construct an antenna using anodised aluminium (aluminum for US readers) for the radiating element. Take some smaller (non resonant pieces) and mount them some distance away from the antenna but exposed to similar environmental conditions. Leave for a year or so and then examine the radiating element surface and compare with the samples. Is there any difference in the surface structure?

The samples should be non resonant, of the same batch material as the antenna and arranged so that they are not likely to radiate or absorb RF energy from the test antenna, while still being exposed to the same weathering and other factors as the test antenna.

Mike G0ULI
Using anodised al

The ARRL Handbook and Antenna Book contain the formulas.

> Is stub matching not the answer?

How about replacing the stub with a capacitor.

> The antenna is designed for about 450 Mhz, if that helps anyone.

At a point on the 50 ohm coax that is 8.75"*VF from
the 190+j140 ohm load, install a 14.2 pF cap to ground.
You can do it with a stub but a cap is much easier.

As with the convergence of energy vectors described
in the Columbian lectures so is general relativity.
Both are procedures that are being followed
in an effort to find a path to GAT. As I stated before
it often is not the destination that counts but what

one learns on the journey . Both of these procedures
have provided insights to the universe but neither
proved to be the answer for Einsteins main quest
which was GAT. Yes, a lot of theories have been produced
by using these procedures some of which relate to our universe
and some of these theories may prove to be correct
but for the wrong reasons. Such was the making of the word
"theory" which deviates from a standard when considering a "law".
If you review Einsteins work in the search of GAT you will
find that most of his theories by his peers which he often
confided in so he is not immune to error.
With respect to the moon and the sun you are quite correct tho
I was being a bit vacitious, but it does show you are capable
of serious debate when you have a mind to together with sufficient
knoweledge to venture into unknown trails of thought, musings
and deduction.

As far as impedance discontinuity *points* go, a nonsense
question.

How many nanoseconds does it take for a signal to travel
through a dimensionless point???? Well, let's see. What
is the speed of light multiplied by zero? Hmmmm, that's
a really tough one.

At any instant of time the forward voltage on
one side of the discontinuity *point* has a relative phase
difference from the forward voltage on the other side of
the *point*. This relative phase difference is constant as
long as the conditions remain unchanged.

The reason that it takes nanoseconds for a signal to travel
through a 75m Bugcatcher loading coil is that the coil is
NOT a dimensionless point. Mine occupies almost 200 cubic
inches. Loading coils with zero dimensions exist *only* in
the human mind and are impossible in reality.

Using two lengths of transmission line that you have to cut to length,
or build them so that they slide like a trombone.

>Do I have to carve out a piece of coax and then fit
>another one into it, if that makes sense? Won't that be nearly
>impossible to solder?

The trombone line will probably more successful, although more
difficult to accomplish. You would build it out of brass, staged
tubing (4 diameters), with BNC connectors at each end. All quite
complex as I said, but it would suit a far wider range of matching
applications. You would also need a shorted BNC to terminate one of
the trombones so that you had that variation covered too. Use a T
connector set a the end of the drive line, one trombone line goes to
the load, and the other goes to the remaining T connection. You might
be able to get away with this last trombone section and just use the T
and a short run of standard coax to the load - emphasis on "might."
These two trombone lengths should have the capacity to vary over a
range at least slightly greater than half a wavelength. You will want
to build them longer for mechanical reasons. The sliding contacts
will not be very reliable (professional tuners have spring loaded
surfaces).

Welcome to the wonderful world of double stub tuning.

Gamma matching at the antenna would make this vastly easier.

trombone section looks a little out of my league. I'm kind of in a hurry. It's kind of too late to gamma match I think because I've already soldered a connector onto the end of the antenna (its helical, so i can't just reach in there and fool with it much, you know?)

It's tempting to just throw a cap in there, but will a discrete capacitor look as it should at 450 Mhz? Or should I make it out of a transmission line?

I did not know that books documented the Z0 of single wire conductors, I'll look into that, thanks. BTW what is the full title of the APRL? I hear it often (I'm kind of a rookie)

THanks everyone

Mike that is a novel aproach but it does appear that
exposure to the antmosphere of any element cnnot be prevented
i.e. pin hole propargation which is evidenced by my mercedes
plating processes. However the guts of GUT is the unification
of mechanical laws (revolving around equilibrium) with electro
magnetic laws. There is no simpler way to verify that cvonnection
than to verify the required angle for a radiator to produced a
uniform radiation such as horizontal polarization. This is a
direct connection that can now be resolved by the use of computor
programs that follow Maxwell and not the equilibrium dictates

of the mechanical world. That is the test for finality in this quest,
an acceptable unity between the sciences.I am beginning to believe
that most of the participants do nor have a computor program or
even a trust in the results when it shown that is formed around
empirical evalution and not solely on Maxwells laws without
suspect additional conditions.To my mind anybody who is antenna
computor savvy would leap at the chance of determining the structure
of a particular radiator to become a leader in this debate, but
unfortunately there are none. When the programmer involved with Eznec
refutes the validity of accepted mechanical laws or dismisses the
notion of non frictional environments there would appear to be some
merit
in questioning their "corrective" actions which for a viable law such
as
Maxwell's is somewhat fraudulent.
For the same person to descend into personal attacks in defence of
his posture certainly suggests that his limits of viability.
have been some what strained

if you have an instrument that is good enough to read the impedance like
that just try experimental values... a foot of small coax is around 20pf,
unfortunately that is a significant fraction of a wavelength so it will act
more like an open stub than a pure capacitor. try just putting a foot in
parallel with the feedpoint and snipping it shorter a bit at a time to see
if it helps.

Cecil,

I believe you said you saw about a 7% shift between the two inputs to your scope. If the 75 meter frequency was 4 MHz that shift would correspond to a time delay of 17.5 ns. Not 3 ns, but not 25 ns either. Is that just an estimate based on rounding to the nearest 25 ns?

This entire issue has become one of counting angels on pinheads, at least from a numerical view. One angel more or less really doesn't matter.

73,
Gene
W4SZ

To put it mildly, you are in a world of hurt.

As Dave points out elsewhere, if you have the instrumentation to measure to the implied accuracy (or at least resolution) as is suggested in this subject line; then you should cut-and-try.

As for capacitors, don't even think of anything but surface mount. But where? You are back into that world of hurt if you don't have the time to do it right (a simple gamma match).

It could be as easy, however, as crushing or spreading the first couple of turns of the helix, or playing with the proximity of the ground plane, or both. If you don't have time, then you certainly shouldn't be playing with caps.

So does this new question rule out the cases (previously
accepted) where the 0-j567 is obtained with 46.4 degrees
of 600 ohm line or 10 degrees of 100 ohm line? These are
not lumped capacitors.

Some consistency that persists longer than one post would
be valuable.

Your time would be better served in pursuing the simpler physical
manipulations of the existing design.

If you have more time, research google with the keywords
gamma match helix antenna.

Telling you "what" it is would be less productive to simply looking at
examples as I perceive you are results oriented. This is an end of
quarter requirement, isn't it?

Actually, you said much more than that, some of
which was quite wrong. And you are right, some
of the errors would be entirely consistent with not
understanding amplifiers. Especially the
superposition ones.
But then why not take the opportunity to learn?
Instead of arguing from a point which you now
claim was ignorance.

yep its an end of the semester project. BUT, we never learned anything about impedance matching, so I feel no shame in asking people like yourself. Thanks for your help.

I'm at home now, and from what I can tell, I can get a good reactive match by changing the length of the wire from the ground plane to the connector? (while keeping the wire from the helix to the connector constant? I think I will try this.

The real part I'm not too worried about.

The shame is your course approaching the topic to the point of
construction without introducing matching! Only the most trivial
designs escape this necessity.

This, however, may suggest that the particular assigned helix design
was already selected to match, and that your construction, or its
measurement are problematic.

It may be in the measurement given that at this scale (if you in fact
observed scale EXACTLY), it is generally no more complex than
assembling tinker toys.

You may have skipped the step of normalizing your network analyzer
(which I presume you have one, given the resolution of your citation
in the subject line), or you failed to isolate the antenna from the
feed line (aka choking the feedpoint, rather more an archaic term for
students, but well known by those practiced in the art). Both amount
to the same thing.

How can you "tell?" The reactive is rarely disassociated from the
real.

>The real part I'm not too worried about.

You should, as it is as much a problem as the reactive part.

I'm worried about the real part, its just that after the reactive part is nice, I don't think matching the real part will be hard.

I've just been reading on the internet and stuff about gamma matches and at least one of them has said that gamma matches only match the reactive part. from what you say I guess this is not true?

Hopefully I can get up to school later and read some real material, but for right now the internet is all i have.

We weren't given a concrete design. More like make a helical antenna with 12db forward gain at 450 MHz--that's it.

I'm about 99% sure that we set up the analyzer correctly. We tested some dummy loads (like opens, shorts, etc) on end of the feedline and they showed up as expected on the smith chart.

Finally, I kid you not. Nothing about impedance matching in this class. I know a little about L networks and the like, but I don't know how to implement these networks at high frequenices.

> So how many nanoseconds does that 36.6 degree phase shift represent?
>
> 8-)

In this example, we have transmission lines, not an antenna or antenna coil. The total phase shift is 90 degrees or 62.5 nsec. The 10 degree 100 ohm line contributes 6.94nsec, the 43 degree 600 ohm line contributes 29.86 nsec. The discontinuity (which is really the effect of loading an 600 ohm open circuited line with a discreet capacitor of X(C) = -j567 ohm ohms) is 25.69 nsec.

6.94 + 29.86 + 25.69 = 62.5 nsec

As long as we know the 600ohm plus 100 ohm transmission line was measured to be resonant at 75m (90 degrees or 62.5 nsec at 75 m), then the contribution of the 'discontinuity' is 25.69 nsec.

Above I am mixing 2 different models: lumped components (at the discontinuity), and transmission line theory. Bringing a coil and stinger into the picture requires using 3 models (antenna radiation) and becomes more complex. I think it is reasonable to do that too but several corrections must be made and you must keep track of the degrees (like you must keep track of the dollars in the hotel room = $30 example mentioned earlier). Still, the 600ohm-100ohm transmission line example helps give one

a conceptual idea of what is happening; phase shifts can and do appear at discontinuities of transmission line impedance discontinuities. I find that interesting, don't you? Here is a lossless phase shift given, as Cecil say, 'free' by nature. Using a smith chart, which is really a graphical means of performing tedious calculations that I am much too lazy to perform, gives one an excellent conceptualization assuming that you have reasonable confidence in the initial measurement that the system as a whole yielded 90 degrees (62.5nsec at 4 MHz).

Yet more stinking dishonest quoting from Cecil. What I ACTUALLY wrote was:

"Likewise there are no glitches in the standard circuit models for inductance and capacitance. They work just fine, for all cases where the dimensions of the circuit are very small with respect to the wavelength, so that distributed effects and radiation are negligible. Where those assumptions are no longer accurate, we can extend the simple model to include some corrections. But the most important point is, we always know that we're building up from a solid foundation."

There's no debating with that man. I've made my technical points, and I'm out.

That is a comforting illusion, but only an illusion. If you are versed with the Smith Chart (another archaic tool from the student's perspective, but immensely used by the practitioner), then you would appreciate this.

If this course is more than a side-bar to your studies (or if you are progressing into RF or Linear design), then the Smith Chart is your best friend.

>I've just been reading on the internet and stuff about gamma matches
>and at least one of them has said that gamma matches only match the
>reactive part. from what you say I guess this is not true?

Only partially. You need to read it again to see if that reference was in fact focusing on removing reactance (it does, as that is one purpose) while soft pedaling resistance (which for the example may have been sufficient).

>Hopefully I can get up to school later and read some real material,
>but for right now the internet is all i have.

It should do quite well.

>We weren't given a concrete design. More like make a helical antenna
>with 12db forward gain at 450 MHz--that's it.

The Helical antenna was invented by a Ham, who is also one of the most respected professors of RF and antenna engineering, John Kraus, W8JK.
Google
kraus helix antenna
One of his students, also a professor in RF and antenna engineering, J.C. "Mac" Mc Laughlin, N8TT, contributes to this group as well. (You would do well to check your school's teaching directory.)

You are probably close enough, within an hour's drive, to knock on his door at the University.

>I'm about 99% sure that we set up the analyzer correctly. We tested
>some dummy loads (like opens, shorts, etc) on end of the feedline and

That should be sufficient.

>Finally, I kid you not. Nothing about impedance matching in this
>class. I know a little about L networks and the like, but I don't
>know how to implement these networks at high frequenices.

It's just at a smaller scale. A stereo microscope can be an useful
aid. The trombone lines are not that problematic either and could
merit extra credit if your scores are a bit shy.

> has been some what strained

Hi Art,

Provided that the antenna and sample pieces are exposed to the same
atmospheric effects, gross damage such as random pinholing to the surface
will be identical in all pieces. However I believe that the antenna element
should additionally show a regular pattern of disturbance caused by standing

waves which might be identified using electron microscopy or just possibly a high power visual microscope.

Computer modelling has its place, but all computer models are constrained by the constants and formulae used to calculate the final results. When the computer model does not agree with physical measurements in the real world, then one of three conclusions may be drawn. The wrong data has been entered, the real world measurement is in error, or a previously unknown variable needs to be taken into account and added to the computer model. Of the three possibilities, the last is the most unlikely if the model is mature and correctly predicts the behaviour of known, experimentally proven systems.

In order to successfuly add a new calculating method to a computer model, it must correctly match the existing results while also correctly predicting the new previously unknown behaviour. This is not a trivial task and it is insufficient to just add a correction factor as this just demonstrates that the true nature of the problem is not understood.

NEC based programs follow well proven principles, but are not the holy grail in being able to predict the performance of all antenna types or configurations. They can accurately predict 'established' antenna design performance in most circumstances and give a useful insight into what properties a new and previously untried design might have. The programs are, of necessity, constrained by the accuracy of the physical measurements and formulae used in writing the original program.

I do not consider the challenge to Newton's Laws to be valid. Just because there is no true vacuum anywhere in the universe, as far as can be established, then all objects will eventually come to rest due to friction. This does not invalidate the premis that in the absence of friction or any other external influence, an object would continue in motion along a straight path forever.

Ultimately whatever predictions are made by computer modelling programs or theory, the only measure of success is by physical measurement in the real world.

Hi Dan,

Having been an RF instructor for a number of years, it is a shabby
intent when it impedes the graded deliverable.

Now, if this was in fact a beginning of the semester assignment; then,
yes it would be a commendable side goal. However, with the statement
of the total absence of matching coverage, it suggests a rather myopic
view of antennas. In a course of 16 weeks, its introduction could
hardly consume more than 5%. More could be discussed, certainly; but
this minimum is hardly prohibitive.

Hi

I consider 160+j140 to be an impedance that would be too difficult to
match to 50 ohms. Any small error will produce a major variation from 50
ohms. Would you consider re-designing your Helix?

Dr Cebik has a good article on Helix Antennas at
http://www.cebik.com/ao/ao15.html.
VE3NPC has published alot of information on how to match helix antennas.

I have some AMSAT Journals with some of VE3NPC "blueprints" of 450 MHz
helix antennas. I'd scan the pages for you if you cant get his article
thru the Internet.

As an instructor, it is none of the instructors "damn business" how a student learns ... only that he does learn and can prove it--usually the avenue chosen is a test.

This makes sure the "instructor" is not inclined towards "tipping the scales", favoring "teachers pets", "assisting" cronies offspring, etc.

However, in the political world of amateur radio where the "good 'ole buddy" system used to rein--there is not enough moral/ethical fiber to see the reasons ...

Darned good logic from beginning to end
Except if logic produces an answer that the
group will not recognise it would be hopeless.
Before even embarking on such a journey someone will say
that I hung a piece of wire from my gutter and you will get

the same results or for that matter a capacitive top hat is better
so it is your mission to prove it isn't. Do you really
think we could bring the members up to par in physics in
what remains of our lifetime?
I will hold your jacket!

> to the ground. Will this have any addition affect?

Yes, the tower's connection to ground can have quite a profound effect on how it interacts with the antenna. And unfortunately, that can be the most challenging part to model.

If you put the bottom of the tower at Z = 0 when using any kind of ground except perfect, you'll get the equivalent of a ground connection with an unpredictable resistance (or an open circuit, depending on the GE "card" parameter). About the best you can do is to use Sommerfeld type ground and put some radials just above the ground. Of course, the problem then becomes estimating the actual tower ground system resistance and the resistance of the modeled radial system. You'll probably end up trying a number of configurations which hopefully include something representing reality, and assuming that the actual system will behave somewhere within the range of the results you get.

There's a fair amount of information about ground system modeling in the EZNEC manual, available in the free demo version. EZNEC's "High accuracy" ground is the same as NEC Sommerfeld ground.

No, but they are an electrical 1/4WL, not any
other length. The electrical length of a stub
is whatever it is. If it is not 1/4WL, it is
some other length. Why is that difficult to
understand?

Sorry, I didn't do that. My only point was that
one could indeed track the energy in the amplifier
if one understand where the destructive interference
is vs where the constructive interference is. Every-
thing I said is based on the conservation of energy,
not on the design of the amplifier.

Only with great stretching.

> The 10 degree 100 ohm line contributes 6.94nsec,

Correct.

> the 43 degree 600 ohm line contributes 29.86 nsec.

Correct.

But now think in the time domain for a bit.
29.86 nsec after the signal is first applied it reaches the

discontinuity. 29.86 nsec later the first reflection arrives back at the start. 13.8 nsec later the first reflection from the end of the 100 ohm section arrives back at the start. It takes many more reflections of reflections before the impedance at the input starts to look like a short.

Nowhere in here will you be able to find anything that happens in 62.5 nsec.

This is quite unlike an actual physical 1/4WL stub where the first reflection does arrive back in 2 * 62.5 nsec. And the impedance at the input behaves like a short after exactly 125 nsec.

Of course the ultimate is an actual short, where Cecil's 90 degrees happens immediately.

These 90 degrees that Cecil insists are "always" present are quite difficult to locate.

According to the Smith Chart, an L network with a shunt L of 70 nH and
series C of 3.2pF or a shunt C of 3.5pF and a series L of 39 nH will
do it. Physically stubs on a circuit board would make sense. Consult
microwave text books for details.

They are used daily by a very large number of people to predict, with excellent accuracy, how new and untried antenna designs will work.

> The programs
> are, of necessity, constrained by the accuracy of the physical
> measurements and formulae used in writing the original program.

That's not quite correct. The "formulae" used are very fundamental electromagnetic equations. The "physical measurements" used are fundamental constants such as the speed of light and permittivity and permeability of free space, all of which are known to much greater accuracy than antenna performance measurements are capable of delivering. So neither constitutes any real constraint on program accuracy. The main constraints are the inability to model all physical structures. For example, NEC has no provision for including a slab of dielectric, making microstrip antennas impossible to model accurately (except the rare ones with air dielectric). There are many such constraints, of which the user has to be acutely aware. The programs are very accurate if, and only if, the model is indeed representative of the physical antenna.

This would be funny if it weren't sad. This newsgroup is one of the few places I can think of where the silly statement I posted about moving bodies and friction would be taken seriously. But it's really no surprise, since it's much less unreasonable than the imaginative alternative theories which are seriously presented, and just as seriously argued, here daily.

My postulate about objects in motion was a parody of Cecil's rejection of theoretical cases on the basis that they can't exist in practice, my intent being to show how such a rejection leads to incorrect results.

But I see it's drawing the same serious response as Cecil's and Art's postings. All that's missing is one of Richard's quotes from Terman and support from Derek.

> Ultimately whatever predictions are made by computer modelling programs
> or theory, the only measure of success is by physical measurement in the
> real world.

That's almost true. It's important also to know that even moderately accurate antenna measurements are extremely difficult and exacting to make. Consequently, there are often cases where model results are a better indicator of an antenna's performance than measured ones. Antennas and models follow the same physical laws. So to the extent that the model imitates reality, the results are the same.

This philosophy isn't restricted to antenna modeling. Circuit designers use programs to model circuits which can't be measured. I've designed circuitry which operates from a few GHz to several tens of GHz, which is still in production. It's simply impossible to measure voltages and currents in such circuits, so modeling is heavily used. Often, every PC board or hybrid circuit pad and trace has to be included as a transmission line model; I've even had to build a transmission line model of a capacitor which was 80 mils long. That the overall performance matched the models' predictions is evidence that the models matched the physical circuits. IC designers rely entirely on models to predict the performance of circuits which can be measured only after huge financial investments to commit the model results to physical reality. The principles are exactly the same for antenna modeling as for circuit modeling.

Respectfully disagree.

I have met people who can explain quantum theory in a manner that a normal high school student can understand.

I have also met people who make sharpening a pencil incomprehensible.

If a person cannot explain something so that an another intelligent person can get at least a rudimentary grasp, the fault does not lie with the person looking for the education.

And when I want to craft field designs, I use the appropriate tools
there too. My current explorations are at the low visible band
frequency of 4.54E+08 MHz with materials measuring 1nM by 1nM by 4nM.
Results are coming along without complaint (aside from segment
lengths).

My point entirely - It is impossible to take into account absolutely every
factor that someone might want to model. It is either so esoteric as to be a
'one off', or someone wishes to work outside of the constraints of accepted
design principles.

I think we are in agreement Roy that the doubts cast on computer modelling are generally raised by those who have an incomplete understanding of the problem they are trying to model. While it may be fun to chuck in some random figures to see what happens, the results are unlikely to be of use without a thorough understanding of the basics. That only comes through a lot of hard work and experience.

Cecil,

Sorry, English is not my native language this month. I must have
misinterpreted the following message sent by you (11/30/2007, 3:35 pm).

****

Jim Kelley wrote:
> Cecil Moore wrote:
>
>> I measured a ~25 nS delay in a 75m bugcatcher coil.
>
> What did you use to make that measurement? (I hope you don't say you
used a Bird Wattmeter.)

I've described it before. I used a dual-trace
100 MHz O-scope and estimated the phase angle
between the two traces at about 7% of a cycle.
That phase angle was certainly NOT ANYWHERE
NEAR the 4.5 degrees reported by W8JI.

W8JI measured a 4.5 degree phase shift in the
standing-wave current being used for the
measurement although virtually no phase
information exists in the standing-wave current
phase. W7EL made exactly the same mistake in
his measurements. No wonder the two agree.

That is why you need to use the smith chart (or perform the tedious calculations). The values returned back to the feed point are superimposed in the time domain, adding and subtracting, but the whole system should (*does*) still act like a 1/4W stub at 4MHz. A 1/4W stub could consist of 1..N series transmission lines of different impedances provided they were cut to the correct lengths.

Remember, the system was *measured* to be 1/4W so the reflections must cause a short every 125 nsec, no matter what is happening in between.

The task is to use the math to verify the measurement. The smith chart and phaser diagrams should work and are equivalent to using math. Time domain is possible too but no way I would ever go to that trouble on usenet at least! Or do you think the measurement was wrong?

Well, I know what I mean by 1/4WL and in my
definition there is no way that (46.4 + 10) = 90.

However I am trying to help you articulate your
definition in a way that is sufficiently precise
that I can use it to determine what you would
consider to be 1/4WL. Unfortunately, at the
moment, it is sufficiently fuzzy that the only
way to determine if something is 90 degrees
(according to your definition) is to ask you.
The need of an oracle to answer such questions
is not the basis for sound science.

Tautologies such as "If it is not 1/4WL, it is
some other length." do not further the definition,
but are good if you want to keep the job of
oracle.

...Keith

Chuckle I made the "mistake" of measuring current, the definition of which can be found in any elementary electrical circuits text. Contrary to Cecil's objections, phase is a property of periodic steady state current (as can also be discovered from reading a basic text), and certainly can be measured. I measured it and so did Tom, but Cecil sure doesn't seem to like the results. Cecil's and his scope are apparently able to measure something else -- whatever it is, I'm afraid my scope doesn't have the magical properties needed to measure it.

I did, however, do at least a couple of things which Cecil might have overlooked. One is that I was careful to terminate each of the current probes with a low-resistance low-reactance load to reduce the insertion impedance to a very low value. Another is that I put both probes on the same wire to verify that their outputs were in phase. These steps alone might have broken the magic spell necessary to measure whatever different kinds of current Cecil imagines.

Can anyone point me to any reference to "standing-wave current" in any reputable text? As far as I can tell, it's something Cecil made up to mean whatever is necessary at the moment to discount others' measurements. It seems to be working quite well -- in the endless discussions, he's trotted it out many times without anyone to my recollection even asking him what it is and how it differs from the current described in textbooks (you know, the rate of charge flow?). Or why "virtually no phase information" exists in it. A periodic waveform with no phase information? Huh?

There's no mystery about traveling or standing waves -- both are very well understood, mathematically rigorous, and have been used for over a century with great success in the design of countless real things that

work. But muddled "standing wave currents" and bouncing waves of average power, supported only by hand waving and misdirection, don't bear much resemblance to the highly developed, rigorous, and self-consistent body of knowledge that's served us so well for so long.

But each to his own.

Roy Lewallen, W7EL

This experiment presents some challenges, particularly
the need for current probes, but I have some questions
on the physical arrangement of test circuit.

You appear to think of the coil as a section of transmission
line, having assigned it a Z0 of 4kohm. But a transmission
line has two terminals at each end. I only find one at each
end here. How is it that this exhibits transmission line
behaviour?

The auto transformer would appear to be unnecessary
since any reflections at the source end will simply add
to the forward signal which will appear at the output

and therefore compensate perfectly when comparing
the input and the output. Proper termination of the
output is necessary because reflections there may
alter the measurements. Leaving out the transformer
would simplify the experient. Do we really need it?

The circuit layout seems to just have a wire from
the bottom of the resistor back to the source. This is
only appropriate if you are assuming that all
components can be treated as lumped (and the
wire ignored) at the frequencies and component
size of interest. But I thought your main argument
was that these components were sufficiently large
that they could not be treated as lumped. If this
is the case, then the routing of the return wire
will have significant effects on the result. How
did you route this wire?

If the coil can be treated as a transmission line,
then the delay can be measured by simply sampling
the voltage at the input and the output. This will
be a much easier experiment than measuring the
current. Should I expect the same results if
I measure the voltage?

Mike ,
I agree with you, it is my fault but one I cannot rectify.
After having a life without medical problems one suddenly
go thru one after the other. Physical problems you can
find a way to accomodate or adjust for them. Mental problems
are a different animal when you can't read a book because
your memory doesn't extend to the end of a line. To boot
this has left me bipolar which you will have to read up for yourself
but now external stress has a larger impact on your life tho in
the last month I have been questioned more than once at hospital
on the living will of my wife you fortunately has survived a
few large hurdles. I am not asking for sympathy as I can handle
adversity
but not in the way I used to do since I am a shell of who I was.
Fortunately I have few worries, no debts,a couple of mercedes
and this laptop and a loving family who dotes upon me.
There are some on the group whose minds are agile enough
to make concessions with respect to my postings. Others of
different backgrounds have difficulty but it is something
I cannot correct, only time can do that and I have little left.
Again, just explaining the complications that I have personaly
but at the same time stating that in myself I am a satisfied
and happy man and bear no ill will to anybody and very,
very proud to be an Englishman.(yes I am a US citizen)
I will leave it at that and that will be the end of my
personal explanation

Best regards
Art Unwin KB9MZ...xg (uk)

Even the ARRL extra class study guide Chapter 9 shows the relationship between voltage standing waves and current standing waves in a transmission line. If you respond that this is not a reputable text (but I think it is sufficient for this fundamental issue), Google will reference numerous reputable papers dealing with standing wave currents.

> periodic waveform with no phase information? Huh?

Roy, this is the part I don't understand about some people posting on this thread. A standing wave does *not* have a phase shift. The standing wave stays in a single position and oscillates. The forward and reflected waves are traveling. An excellent conceptualization of we mean by "standing wave" with its constructive and destructive interference can be seen here:

http://www.chemmybear.com/standing.html

My only problem is, you are the antenna software design guru. I know I must be missing something big here because I would expect you to be telling "others" this stuff.

> But each to his own.

Note the assertion on the graphic that two waves can be at the same place at the same time (a subject of a different thread), something I agree with :-)

Of course, those are *physical* degrees. We are
talking about *electrical* degrees. It is impossible
to get the reflected wave in phase with the forward
wave unless there is an electrical 90 degree phase
shift.

If you lay the 43.4 degrees out starting at Z=0
toward the load on the Smith Chart and lay the
10 degrees out starting at Z=infinity toward the
source, you will observe the phase shift caused
by the impedance discontinuity.

> ... the only
> way to determine if something is 90 degrees
> (according to your definition) is to ask you.

All one has to do is plot it on a Smith Chart
and the number of electrical degrees is obvious.
If you don't know how to use a Smith Chart it
might be time to learn how.

Mike let me put things into perspective. I use the programs a lot
and trust them. At the same time there is an article in a compendium
that relates the difficulties they have had with calculations meeting
empirical solutions.They then added a condition which infers that
the time varient used is that of the current.But when I used the
computor
by following Gauss and the terms of equilibrium the result is a tank
circuit which contradicts the added condition. So in a sense the
program corroberates my work despite the imposed condition which
the program itself describes as erronious.
When I read of the difficulties associated with antenna programs
and how they were adjusted especially with an erronious condition
which is not allowable in mathematics then the corroberation of
my work is seriously strained to what appears as the correct results
for the wrong reasons. A specific case is where using magnetic and
electrical standards one can use vectors in a known direction
the summation of which is not parallel to the axis of the radiator.
The paradox is that the computor results are in line with Maxwells
laws
when one is confined to a situation of equilibrium demanded by Gauss.
Thus the question is how can this be if the program itself has
imposed
a condition around the laws of Maxwell whereas the program itself
overrules the validity of that same condition.
This obviously leaves the computor analysis in a precarious position.
For myself I would like to know how the programmers implemented this

condition they imposed and how it affected derived results.If this
inconsistency is not resolved to my satisfaction then the thesis
is tenacious at best and subject to serious question.
Best Regards
Art Unwin KB9MZ....xg (uk)

Or do you mean that the amplitude of the standing wave does contain phase information about phase 2 other waves, the forward and reflected waves, relative to each other? Is that what you are saying (making this a semantic issue again)? The standing wave itself is at zero phase angle.

"Transmission Lines", by Chipman, Chapter 8

> A periodic waveform with no phase information? Huh?

Yes!!! Here's what Chipman says on page 159: "V(d)=A*cos(Bd).
This expression indicates that in the voltage standing wave
pattern produced on a lossless transmission line by a voltage
reflection coefficient, rho, at the terminal load end, the
phase is constant over any half wavelength of the pattern
between successive points of zero voltage magnitude, ..."

The same is true for the current standing wave pattern on
a standing-wave antenna and means that constant phase current
cannot be used for delay measurements.

"PHASE IS CONSTANT OVER ANY HALF WAVELENGTH" including the
part where the coil is located.

Please look at the phase of the current in a 1/2WL dipole
and tell us how to use phase measurements of that current
to determine the delay through the 1/2WL dipole wire.

> There's no mystery about traveling or standing waves ...

Roy, please explain the phase shift reported by EZNEC for:

http://www.w5dxp.com/coil512.ez

Use the "Load Dat" button to view the phase shift.

The equation for a single-wire transmission line over
ground is well known to be Z0 = 138*log(4D/d)

As a data point, take a look at:

http://www.w5dxp.com/coil512.ez

Here is the current for each turn as reported by EZNEC.

Load 1 Current = 1.02 A. at -3.15 deg.
Load 2 Current = 1.121 A. at -11.28 deg.
Load 3 Current = 1.211 A. at -17.09 deg.
Load 4 Current = 1.289 A. at -21.59 deg.
Load 5 Current = 1.352 A. at -25.22 deg.
Load 6 Current = 1.401 A. at -28.29 deg.
Load 7 Current = 1.436 A. at -31.0 deg.
Load 8 Current = 1.459 A. at -33.5 deg.
Load 9 Current = 1.47 A. at -35.89 deg.
Load 10 Current = 1.468 A. at -38.25 deg.
Load 11 Current = 1.454 A. at -40.66 deg.
Load 12 Current = 1.427 A. at -43.21 deg.
Load 13 Current = 1.387 A. at -46.04 deg.
Load 14 Current = 1.332 A. at -49.34 deg.
Load 15 Current = 1.261 A. at -53.5 deg.
Load 16 Current = 1.17 A. at -59.25 deg.
Load 17 Current = 1.057 A. at -68.49 deg.
Load 18 Current = 1.039 A. at -71.74 deg.

> The auto transformer would appear to be unnecessary
> ... Do we really need it?

I don't know the answer to that question. I didn't
want any reflections from the coil.

> How did you route this wire?

I used an aluminum ground plane for that "wire".
Since the wire is very short at 4 MHz, I assumed
not much transmission line effects in the wire.

> Should I expect the same results if
> I measure the voltage?

I doubt it. But the subject was the current through
a loading coil, not the voltage.

Robert A. Chipman agrees with you. He says the standing
wave phase is "... constant over any half wavelength ..."

Kraus also agrees. Here is a graphic from Kraus' book,
"Antennas", showing the lack of phase shift over the length
of a 1/2WL dipole. Essentially the same thing would be true
for short loaded dipoles and loaded mobile antennas.

http://www.w5dxp.com/krausdip.jpg

Roy admitted some time ago that EZNEC reports that
same constant phase for current over the entire length
of a 1/2WL dipole yet he still insists that same current
can be used to measure phase-shift/delay through a coil
when it cannot even be used to measure the phase shift
through 1/2WL of wire.

You've described a standing wave, but haven't defined any special kind of current known as "standing wave current". A standing wave isn't a current, it's the shape of the magnitude of the voltage or current as a function of position. I'm sure you can find multiple descriptions of this on the web, with some being correct and well done, some being totally wrong, and others at all points between. I tend to look to published texts for accurate information, and currently have about 14 reputable texts involving transmission lines and electromagnetic waves on my bookshelf. I surely might have missed it, but I don't recall ever seeing a reference to "standing wave current" in any of them.

The nature of a standing wave is well known. It describes the envelope of the distribution of voltage or current on a transmission line resulting from the sum of forward and reverse traveling waves along a line not terminated in its characteristic impedance. This envelope, which has a physical periodicity along the line and which is sinusoidal in shape only if the SWR is infinite, appears to stand still except for increasing and decreasing in amplitude at the same rate as the traveling waves which cause it. So "standing wave current" translates to "envelope of an interference pattern current". There is no special kind of current known as "standing wave current" because the combination of words is meaningless.

Traveling waves interfere to cause the standing wave envelope, as I hope your web references tell you. When you measure the current at some point in a transmission line, you're measuring the current at that point, period. Not "traveling wave current" or some other special kind of current. The current at any point along a transmission line has a magnitude and a phase relative to an arbitrary reference. Both can be easily calculated from basic transmission line principles. You can do it directly or by adding forward and reflected waves to get the total -- if

you get different results by using the two methods, you've done
something wrong.

For the record, I measured some currents in a wire on both sides of an
inductor at the base of an antenna a couple of years ago and posted the
results here. One of the things I measured, with some care, was the
phase angle between those currents. I didn't "mistakenly" measure
"standing wave current". There is no such thing. I measured sinusoidal
currents, which have phase and magnitude, at two points. The
measurements agreed quite closely with results predicted from
conventional theory. I never was able to tell whether they agreed with
Cecil's theory because he kept changing his predictions.

> Note the assertion on the graphic that two waves can be at the same place at
> the same time (a subject of a different thread), something I agree with :-)

You'll have to run that one by Cecil. He's said many times that
traveling waves bounce off each other when they meet. That behavior
seems to be necessary to support one of this theories.

Hopefully my other posting has mostly answered this.

The total current is the sum of forward and reflected waves. The magnitude of this total has a periodic distribution, or envelope, alsong the length of the line known as a standing wave. You can learn certain things about the line and load by looking at the magnitude and position of this envelope. The position of the envelope can very reasonably be termed its "phase", although like the envelope making up the "wave", it's a positional phase rather than a time related one. But neither the amplitude nor the "phase" of the envelope known as the standing wave will, by itself, tell you anything about the phase of the current at any point along the line.

Confusion among the wave-like envelope of the standing wave, moving traveling waves, positional and time related phase, and other potentially ambiguous terms has been instrumental in sustaining confusion about issues that aren't really very complicated.

"Standing wave current" is the current that exists in standing-
wave antennas and stubs. It's phase is constant and cannot
be used to measure phase-shift/delay. EZNEC agrees.

Here is Kraus' graph of standing wave current.

http://www.w5dxp.com/krausdip.jpg

This is a graph of the currents you used for your measurements.
Note the virtually unchanging phase.

> For the record, I measured some currents in a wire on both sides of an

EZNEC says that the phase angles of the currents you measured
are unchanging. An unchanging phase is useless for measuring
phase shifts.

Earlier, I had written:
"Likewise there are no glitches in the standard circuit models for inductance and capacitance. They work just fine, for all cases where the dimensions of the circuit are very small with respect to the wavelength, so that distributed effects and radiation are negligible. Where those assumptions are no longer accurate, we can extend the simple model to include some corrections. But the most important point is, we always know that we're building up from a solid foundation."

Hi Dan,

Keith was quite specific to separate the transient state from the steady state such that a short is not available "every 125 nS." Most 125 nS, perhaps, but not initially and so not "every 125 nS." Trivial distinction on the face of it, perhaps. When paired up with an absolute statement that has been "proven" to be universally true, then trivial is enough to sink the Titanic.

>The smith chart and
>phaser diagrams should work and are equivalent to using math.

There are two solutions: transient and steady states; there are two maths. Cecil, in the same breath, manages to jump from one to the other enough that you should be acquainted with both by now - or you will be when you suddenly find yourself facing a paradox: Like why is the band that is playing "Nearer, My God, to Thee" is at such an odd sloping angle on the boat deck?

Fortunately it takes only a little effort to follow one line, and to drill down to an absurdity. His proving Tom's delay was no better than his own measurement demonstrated this easily. The drilling down was in simply noting the particulars and skipping all the fluff of trivial sidebars. Most folks find the fluff attractive and chase it to no conclusion instead (that is how this thread accumulated 600 postings).

Keith, on the other hand, has the discipline to simply stick to one issue, and drill down. Patience brings rewards in the end.

>standing wave currents

Hi Dan,

When these three keywords are braced with quotes, Google reveals all of 19, non-duplicated sources. Not a very compelling testimony to this phrase's usage when the phrase "current standing wave" results in at least 10 times that amount. Even more so, neither amount to many references.

When googling the separate term Current from the phrase "standing wave;" then the hits count climbs through the ceiling to nearly 200,000 links or 1000 to 10000 times the unique phrases above.

Simple deconstruction would suggest that
>standing wave currents
is about as useful as downloading a windows patch from www.micorsoft.com. Would you? (Try the link and see if you would trust the source.)

Deconstruction aside, what I see missing in your enquiry into this "current" is any question about what information it contains. I've seen the suggestion of phase, and Roy has answered that, but in isolation (no reference) there is magnitude only. Cecil's reconstructed, but revisionist measurement that disputes Tom's data published on the web; it was nearly identical to Tom's when phases were reconciled in his test arrangement.

Even here in the post you've responded to, Roy demonstrated the normalization of scope channel's separate delays. Given it was his trade for umpteen years in their design (as it was my trade to calibrate them), and Cecil's trade was building flip flops (the only phase there is 180 degrees and nothing in between); then who has a better grasp on the fundamentals? An IQ of 260 doesn't mean anyone is educated or has a skill.

I think it might be useful to say a little more about standing waves.

Imagine a single lossless transmission line with a sine wave source at one end and a load at the other. Begin with a load equal to the line's Z0. Make a graph of the magnitude of the current or voltage as a function of distance from the source. With the Z0 load, the magnitude will be the same all along the line so your graph will be a straight line. This is a "flat" line, with no standing wave. A probe sitting at one spot would show the instantaneous voltage or current amplitude going up and down in a sinusoidal manner. A probe a bit farther down the line would look the same, but delayed; there's a phase difference between the voltages or currents at the two points. The phase difference is equal to the line's physical length in degrees divided by the velocity factor.

Now change the load so the line is slightly mismatched. A standing wave will appear -- the graph of amplitude vs distance won't be flat any longer, but will have a ripple added to its previous constant value. (The VSWR is, by definition, the ratio of the highest to the lowest values of the voltage envelope on a line long enough to have a full maximum and minimum. The current SWR is the same.) The maxima and minima of the ripple don't move, hence the name "standing wave". If we look at the instantaneous voltage or current at a single point, it will go up and down in step with the source as before. If we also look at the second point, it'll also go up and down as before, and there will be a phase angle between the two. But there are two interesting differences from the flat line: One is that the amplitudes at the two points are now unequal unless they're an integral number of half electrical wavelengths apart (or a few other special cases). The other is that the phase shift isn't the same as before. There's still a phase shift between the two points, but it's no longer equal to the electrical length of the line between the points. We'll find that either the voltage has shifted more and the current less, or vice versa depending on the load and which points we've chosen. But at every point the current and voltage still have phase angles which change with position along the line. That is to say, the voltage or current at one point is delayed compared to the voltage or current at the other.

As the mismatch gets more extreme (i.e., the SWR increases), the magnitudes at the two points get more different, and the phase deviates farther from the electrical length of line between them. (This is why you can't expect phased array "delay lines" to provide a delay equal to the lines' electrical lengths when they're not terminated with Z0.)

At the most extreme case of mismatch -- an open, short, or purely reactive load, resulting in an infinite SWR -- the amplitude of the

standing wave along the line goes from zero to twice the value it had when the line was flat. And a really interesting thing happens to the phase of the voltages and currents on the line. Remember how as the mismatch got worse, the voltage and current phase difference between two points got farther and farther away from the electrical line length between them? Well, when the SWR is infinite, it's gotten to the point where the voltage or current phase remains the same for a distance of a half electrical wavelength, then abruptly changes 180 degrees, repeating every half electrical wavelength. Some antennas behave in some (and only some) ways like transmission lines, and you'll find that modeling programs report just this behavior of the phase of the current along a straight wire antenna.

The standing wave and all the characteristics of the voltage and current (e.g., how their magnitude and phase varies with position along the line) follow directly from an analysis of forward and reflected traveling waves on the line. The voltage or current at any point is simply the sum of the two waves at that point, and they have the properties I've just described.

I hope this helps in clarifying the meanings of traveling and standing waves, voltage and current along a transmission line. I'm sure there are lots of good graphical illustrations available -- but some bad ones too. Hopefully keeping this explanation in mind when you look at the nice graphics displays will help you sort the bad ones from the good.

Art

I wasn't having a go at you or your use of computer modelling. The problem is that computer models can only simulate what might be happening in the real world. They cannot take into account every possible situation. Mathematics itself is riddled with logical inconsistancies and we have learned to work around them. Some methods work better than others for solving specific problems.

Cheers

Ahh. So the coil and the ground plane make the transmission
line, and the two terminals are between the coil and the
ground plane.

But I did not see D or d in the spreadsheet which computed
Z0.

> > How did you route this wire?
>

> Since the wire is very short at 4 MHz, I assumed
> not much transmission line effects in the wire.

I'd expect that repeatability will require the same
orientation of the coil with respect to the ground
plane. And the same height.

Of course this horizontal coil has a completely
different relationship to the ground than it would
when installed vertically in an antenna? Will the
results of the measurement be at all
applicable?

The key point is that since 62.5 nsec represents 1/4WL at the
frequency of interest, if the line was 1/4WL long, you would
find things that happen every 62.5 nsec.

> The values returned back to the feed point are superimposed
> in the time domain, adding and subtracting, but the whole system should
> (*does*) still act like a 1/4W stub at 4MHz.

There is no doubt that all the variants discussed do share one
property with a 1/4WL open stub; the input impedance after a
long settling time is the same. But other properties, particularly
settling time, are quite different.

> A 1/4W stub could consist of
> 1..N series transmission lines of different impedances provided they were
> cut to the correct lengths.

Quite true. And if your definition of 14WL stub was anything that
produced a short, I would agree that it is self-consistent
but that it is probably not too useful.

> Remember, the system was *measured* to be 1/4W so the reflections
> must cause a short every 125 nsec, no matter what is happening in between.

If I understand what your are saying, then NO. Consider the short
itself.
There is no delay what-so-ever.

If you are saying that along the transmission line there is a point
every 125 nsec where the impedance is 0, I would agree for
a constant impedance line, but if you change the impedance then
the points on either side of the discontinuity are not 125 nsec
apart.

> The task is to use the math to verify the measurement. The smith chart and
> phaser diagrams should work and are equivalent to using math. Time domain is
> possible too but no way I would ever go to that trouble on usenet at least!
> Or do you think the measurement was wrong?-

I have no disagreement with the resulting numbers.

But 46.4 + 10 does not equal 90. Subtracting (46.4 + 10)
from 90 does not yield a useful number, though if you
decide that the sum MUST be 90 for some reason, then
you do have the number that will do that.

Absolutely nothing dishonest about it.

Once you make a mistake, Ian, it doesn't matter what
you say after the mistake. What I disagreed with was
your mistake and didn't bother quoting the rest. I
believe that is part of the netnews guidelines.

So I challenge you again. Given a two wavelength
slinky dipole, please use your lumped constant
model to predict the current in the antenna.

Of course, you cannot and will not do that.

Ian, your first sentence was false and I responded to it.
No amount of words that you post after the first false
statement will make it true. There *are* glitches in the
standard circuit models for inductance and capacitance
because they do not agree with Maxwell's equations.
There was nothing dishonest about my replies. In fact,
I was just following netnews rules.

You said:
> Likewise there are no glitches in the standard circuit
> models for inductance and capacitance.

But there are glitches in that model so that is a false
statement to which I replied. Nothing you can say after
that statement will make it true.

I am sorry that you get so upset when challenged but
you are wrong about a lot of things.

Except that I have offerred a number of examples
which you, the oracle, have declared are not
90 "electrical degrees".

> If you lay the 43.4 degrees out starting at Z=0
> toward the load on the Smith Chart and lay the
> 10 degrees out starting at Z=infinity toward the
> source, you will observe the phase shift caused
> by the impedance discontinuity.

I, too, can subtract (43.4 + 10) from 90 and get
a number. This does not, by itself, a useful
proposition make.

> > ... the only
> > way to determine if something is 90 degrees
> > (according to your definition) is to ask you.
>
> All one has to do is plot it on a Smith Chart
> and the number of electrical degrees is obvious.

Please provide your algorithm in sufficient detail
that I can test it against the various examples.

So far, each time you have provided a rule, I
have constructed examples according to the
rule which the oracle has declared are not
90 "electrical degrees". Without a testable
rule that successfully distinguishes those
cases which are 90 "electrical degress"
from those which are not, there is nothing.

Having to ask the oracle does not suffice.

And the Smith chart is insufficient. One of your examples began with "take the impedance of 0-j567 and plot it on the chart", which is okay, but it turned out that how that impedance was created is important. It had to be a capacitor (sometimes). No amount of Smith charting will reveal that detail.

A testable rule, please...

I've done exactly that with current using EZNEC. The traveling wave
graph is on the left at http://www.w5dxp.com/travstnd.gif

The standing wave current graph described in Roy's next quoted
paragraph below is on the right. The tabulated data provided by
EZNEC is at the bottom.

If standing-wave current is all that exists, EZNEC faithfully
reports the amplitude and phase of the standing-wave current.

If traveling-wave current is all that exists, EZNEC faithfully
reports the amplitude and phase of the traveling-wave current.

> straight wire antenna.

The question is, Roy, since as you say, "the current phase remains
the same for a distance of a half electrical wavelength", how can
you possibly use that same current to measure the phase shift

through a coil and convert your reading to a delay through the coil? If the phase of the current doesn't change over the entire 1/2 wavelength, it certainly doesn't change through the coil. What you have proven above is that your and W8JI's previously reported coil measurements are meaningless and that the only valid way to measure the delay through a coil is to use the traveling wave current described in your first paragraph above.

What you are saying in the above paragraph is that the current in a high-SWR environment carries virtually no phase information. So the question remains:

WHY DO YOU THINK THAT PHASE MEASUREMENTS OF STANDING WAVE CURRENT, GIVEN ITS VIRTUALLY UNCHANGING PHASE, WILL YIELD ANY USEFUL INFORMATION ABOUT THE DELAY THROUGH A LOADING COIL?

You did measure the phase shift through the coil but the measurement was meaningless and the conclusions invalid. We already knew it would be close to zero and bear no relationship to the delay through the loading coil - BECAUSE THERE IS VIRTUALLY NO PHASE INFORMATION IN THE PHASE OF STANDING WAVES.

The phase information in standing waves is in the amplitude but you obviously don't realize that fact since you continue to talk about the current "drop" through the coil being due to losses, radiation, and leakage to the environment. If there were zero losses, zero radiation, and zero leakage, the current "drop" would still be there as a result of nothing more than the superposition of the forward and reflected waves.

> I hope this helps in clarifying the meanings of traveling and standing
> waves, voltage and current along a transmission line.

I agree with what you have said in this posting. Unfortunately for you, what you said in this posting contradicts and invalidates the conclusions that you and W8JI drew from your phase measurements of current through a loading coil in a standing-wave antenna.

Out of one side of you mouth, you tell us that the standing-wave current phase is unchanging over 1/2 wavelength. Out of the other side of you mouth, you tell us that same current can be used to measure the delay through a loading coil. Please pick one side or the other - they cannot both be right.

Continuing: If your model worked, W8JI would not have
measured a 3ns delay on 4 MHz through a 2" dia, 100 T,
10" long coil. It is, in fact, your flawed model that
allowed him to come to the false conclusions that he
did. And I notice your model got you in trouble because
you did not offer one word of objection to his obviously
impossible conclusions.

You guys are religiously addicted to models that do
not correspond to reality and it gets you into a lot
of trouble including passing false information along
to your naive readers.

It appears that we are on the verge of proving that a
3 ns delay through the above coil is impossible no
matter what your model says.

From: Roger <rsparks@elltel.net>
Message-ID: <sOednVfM9r1Qi8HanZ2dnUVZ_vKunZ2d@neonova.net>
Source record: 31939

Hi Roy,

Could I add this observation? Both traveling waves and standing waves
can be measured. A single volt meter or ammeter will measure the
standing wave which is the sum of the traveling waves.. A DIRECTIONAL
volt meter or ammeter will measure only the traveling wave within the
design direction, but can not distinguish between components from
multiple reflections that might combine.

A directional voltmeter or ammeter will measure the same voltage or
current no matter where it is placed in the transmission line under
steady state conditions, assuming no resistive losses in the
transmission line.

Cecil,

As usual, you continue to take things out of context. That quote specifically referred to the (kz-wt) "phase". Simple examination of the ideal standing wave equation shows my quoted comment to be correct.

However, I have also pointed out on several occasions that there are multiple definitions for phase. It is not necessary to have a (kz-wt) term in order to have valid and useful "phase" in a circuit.

But you already know that.

Hi Roy,

Your description of the Phase and the SWR contribution to how it is
perceived was excellent; and with enough words to get from start to
finish and be thorough.

It deserves acknowledgement.

However, with this buried beneath all the trash of this thread, it
should be included in your own site's miscellaneous files for easier
reference, because the misperceptions for this topic (and Cecil
stepped right up to shove a stick in the spokes) just aren't going to
go away.

In any given situation, many factors may come into play ...

A person may just be so damn ignorant he/she looks to be whamboozling, this is different. Personally, been there--done that--most likely, not for the last time.

But, you know what I mean--self-importance can be a drug which is as addicting as any. Hero worship, guru/child relationships, etc.--I have little use for.

Frankly, I learn more from the argument and debate here than I do from a bunch of "experts" all slapping one another on the back!--drives me to drag out a smith chart and refresh on ohms/mhos and why mhos are now siemens, where to locate the locus and which direction to move, etc.--it won't kill me/us ... I don't personally care if the "experts" are proficient in using one, do-them-in-their-sleep, etc.--I want to do it for myself, make-all-the-standard-mistakes, and come out knowing a bit more than when I walked in--if at times I look like a fool, so be it!--don't hold your breath, I am working on it ...

Regards,
JS

Yes, it is an unbalanced transmission line.

Keith, I want to commend you on having an open-mind and an ability to listen to what I am saying. That is the best way to get down to the technical facts. Others on this newsgroup are closed-minded with an inability to listen presumably because they already know all there is to know.

> But I did not see D or d in the spreadsheet which computed
> Z0.

Those must be secondary effects or else Dr. Corum would have included them. Of course, Corum's coils are operated against a very large ground plane. Corums's equation (50) and (51) for Z0 are only concerned with the diameter of the coil and the wavelength. However, the diameter of the coil is roughly equivalent to the diameter of the wire in a straight-wire configuration.

> I'd expect that repeatability will require the same
> orientation of the coil with respect to the ground
> plane. And the same height.

Absolute repeatability is not necessary for conceptual technical truths to emerge.

> Of course this horizontal coil has a completely
> different relationship to the ground than it would
> when installed vertically in an antenna? Will the
> results of the measurement be at all applicable?

If the range of results is 15ns to 35 ns, that will be a clue that 3 ns is impossible. The absolute results are not important. The spread of measurement values will be enough to prove that 3 ns is outside of any

3 sigma limit.

No, that is not a key point. If we figure out some way
to get a 90 degree phase shift to happen in 10 nsec, so
be it. There is nothing that forces a phase shift to
take the same amount of time as it does in a transmission
line.

> There is no doubt that all the variants discussed do share one
> property with a 1/4WL open stub; the input impedance after a
> long settling time is the same. But other properties, particularly
> settling time, are quite different.

I don't have a problem with that statement. Everything I
have talked about is in regards to steady-state conditions.

> If you are saying that along the transmission line there is a point
> every 125 nsec where the impedance is 0, I would agree for
> a constant impedance line, but if you change the impedance then
> the points on either side of the discontinuity are not 125 nsec
> apart.

If I never said that, your statement would still be true.
I agree and never said otherwise.

> But 46.4 + 10 does not equal 90.

Yet we know for certain that the reflected wave has undergone
a 90 degree phase shift or else it wouldn't be in phase with
the forward wave at the feedpoint. That additional phase shift
has no time constraint. Deduction will tell one where it is
located. It is not in the 600 ohm section. It is not in the
100 ohm section. It is not at the open end of the stub. Since
the only location left is the impedance discontinuity, it must
occur at that point and indeed the Smith Chart shows us that
is exactly where it occurs in an exactly predictable value.
"Elementary, my dear Watson".

If it is 90 electrical degrees then it is 90
electrical degrees. If it is not 90 electrical
degrees, it is not 90 electrical degrees. I don't
know how to make it any clearer than that.

> I, too, can subtract (43.4 + 10) from 90 and get
> a number. This does not, by itself, a useful
> proposition make.

It does if we know the reflected wave undergoes a
180 degree round-trip phase shift or else the
reflected wave would not be in phase with the
forward wave and therefore the feedpoint impedance
would not be purely resistive.

> Please provide your algorithm in sufficient detail
> that I can test it against the various examples.

It's the same as determining if an antenna is 0.5WL
or 1.5WL or 2.5WL or 3.5WL or ... Do you also have
a problem with that?

If the phase shift end-to-end is 180 degrees, the
device is 90 electrical degrees long.

If the phase shift end-to-end is not 180 degrees,
the device is not 90 electrical degrees long.

> So far, each time you have provided a rule, I
> have constructed examples according to the
> rule which the oracle has declared are not
> 90 "electrical degrees".

I have provided no rule. Everything is common sense.
If a dipole is 130 feet, it is 1/2WL on ~3.6 MHz.
If the antenna is 403 feet long, it is 1.5WL on
~3.6 MHz. Why do you have a problem telling the
difference between a 130 foot dipole and a 403
foot dipole?

It would appear that our author has some doubt about the statement
above to have prefaced it with "if." A grammarian would point out
that there is no corresponding "then." As this doubt is obviously a
contorted product of tension, I won't look for spelling errors that
Cecil would expect me to find.

>If traveling-wave current is all that exists, EZNEC faithfully
>reports the amplitude and phase of the traveling-wave current.

Again, the same nagging doubt - "if" indeed.

We can summarily answer that doubt by immediately dismissing it. There
is no such thing as standing-wave or traveling-wave current. The
statements above with the doubting "if" stripped out would read:

The current found in the solution of the standing-wave is all that
exists, EZNEC faithfully reports the amplitude and phase of that
current.

The current found in the solution of the traveling-wave is all
that exists, EZNEC faithfully reports the amplitude and
phase of that current.

Again, drilling down yields another silver plate of low hanging fruit.

Perhaps if Roy would have used a directional coupler to
measure the phase shift through his coil, he would have
realized his conceptual mistake a lot sooner. But his
current transducers have absolutely no directional
capabilities at all.

We are using the EZNEC convention for "phase". Other
definitions do not matter in this context.

Roy simply posted my arguments in minute detail. I agree with it and point out that it also proves that Roy's and Tom's phase measurements using standing-wave current were meaningless as they did *NOT* measure the delay through a coil as asserted by both parties.

Roy's posting is entirely correct. He correctly points out the difference in traveling-wave current and standing-wave current which can be deduced from their different equations. From Roy's own posting, anyone can deduce why standing-wave current cannot be used to measure the delay through a coil, yet last time I checked, Roy was still "standing by" those meaningless measurements and also supporting W8JI's equally meaningless measurements.

Would anyone who cares send Roy an email asking him to make up his mind? He simply cannot have it both ways.

wrote:

>When you are exposed, what will you do then?

Probably take a leak. Oh! You must have something else in mind when
you use the word exposed. Do you have anything that would remove the
cloud from your obscure language?

Is your outrage merely the embarrassment of a failed suicide attempt
with your data wearing a dynamite vest to embrace Tom's? The last
step in making it a successful attempt is a painful admission that you
are both wrong! That conclusion is not so far away as to be false is
it? -faint heart n'er won fair argument- Pull the pin!

It's not like you have actually pointed to any specific datum that was
in error. It's not like you have provided us with any amplifying
details taken from your measurement that converges with Tom's. I've
seen no dispute about the numbers or the typical normalization of an
O'scope. My posting is exceptionally short and entirely based on your
own facts. Your objections would, of course, be solved with you
indicting your own evidence. Was it as bad as perjury? Did you
misread some settings? Were the current probes in the wrong place?
Was there the proximity of a large conductor that disturbed your
results? Did you plug-n-chug the wrong Xeroxed formula? What went
wrong? More importantly: why is it my fault?

Unfortunately, in the last 127 postings you have forever forsaken the
details of your measurement to oblivion and returned to the opiate of
synthetic solutions.

Noting the complete absence of technical substance to your
accusations, your leg must be getting wet by now. Is it raining down
your way? ;-)

> it's the shape of the magnitude of the voltage or current as a function of
> position.

Yes, that is what I have been saying. It is more correctly called a "current standing wave" that is a function of postion. It is not a description of how the current moves with respect to time, it only represents by its amplitude the relationship of the forward and reflected currents in time. For a transmission line that is electricall 2pi radians, I will always measure 0 volts at the feedpoint and the endpoint of the line. I will measure voltage maxima every (N/2)*pi radians where N is any off integer. Current values along the standing wave will always be pi/2 radians out of phase (90 degrees) with voltage.

For an open circuited transmission line, the phase shift between the forward and reflected waves will have to be pi radians. The maximum amplitude will be 2X.

We are talking the same language now. We can agree that the only phase shift information in a standing wave depends on 1) the actual position along the length of the line where the measurement is taken (it must be positioned at a place where there is in fact amplitude variation) and 2) the amplitude of wave at the time it is taken, which gives the relative phase difference between forward and reflected waves. This is not usually a useful thing to do (i.w. who cares?) but it is a response to the semantic arguement as to whether a standing wave contains phase information. It does imply the forward/reverse wave positions in time, therefore tells their phase, but who

cares? It is not useful information and has nothing to do with the delay along the length of a coil.

> terminated in its characteristic impedance. This envelope, which has a
> physical periodicity along the line

One can "call" it periodicity along the line but that is not a good definition of "period". For me, period = 1/f; it only relates to time. A standing wave graphic that shows a wave has a shape with respect to its position along the line but that is not really "periodicity". If you choose any physical point along the line that is not zero, then you will see an oscillation with periodicity (in infinite number of those, the same number as there are non-zero points on the line).

Thank you for you detailed responses and I think we completely agree once we have agreement in our definitions.

The term "waves" isn't very clear. To resolve the issue that current into
the load is zero, a reflected wave of -I and consequently +V is required.
Now which "wave" is "phase shifted pi radians".

> We are talking the same language now. We can agree that the only phase

Hmmm!

Owen

Richard:

The majority of your text has turned to attacking personalities instead of attacking ignorance, "wifes' tales", inaccuracies, mis-calculations, etc.

Not only is this boring, it is plain disgusting. My gawd man, step back for a moment or two and get a hold of yourself.

When you play the Shakespearian-antagonist in this comedic melodrama, I find it amusing and entertaining (if sometimes trying.)

Come back to reality man ... you ain't done nothing yet which we have not all been guilty of at one time or another. I enjoy the debate and the flurry of "boning up on smith charts", don't ruin it for the rest of us ... since I have adopted Arts' "Gaussian Theory", I have to keep iron objects away from my antenna, thats' bad enough! Let us who would like to have some fun--have it! <grin>

A lot of this is above my head, I have to strive to get the tools to understand it--isn't that how it was meant to be when we entered the ranks of amateur radio. I don't want a "Radio Oracle(s)" in r.r.a.a who tells me of visions or "all is already known", it just ruins the mistique, adventure and technical challenge which drew me here ... of course, you are chatting with a fellow which used to listed to "theater radio" on SW--"Only the Shadow knows!"

Besides, it's Christmas!

Regards,
JS

No. If I choose a point on the transmission line in the measured paramenter (say voltage) is not equal to zero (there will be zeros at 0 and 2 pi radians electrical and (physical DISTANCE if VF = 1)), then I will observe voltage maxima that varies as a sunusoid over time. Graphically, it is a value that oscillates "up and down" about the point. These maxima vary but are at 2X (Vf max and Vr max) at pi/2 and 3/2pi DISTANCE. Let me choose pi/3 as a measurement point. I have not calculated the maximum amplitude of the sinusoid is at pi/3 radians DISTANCE but it doesn't matter: When the sinusoid at pi/3 rad is maximum, the relative phase shift of the forward and reflected voltages is 0 degrees, or 180 degrees etc. etc.. When the amplitude of the sinusoid is zero at pi/3, then the phase shift is 90 degrees relative to forward and reflected waves. When the amplitude of the sinusoid is at any value in between, it will correlate to relative phase differences of forward and reverse waves at any angle in between. This has nothing to do with coil delay.

The same situation above applies to current except that all values are shifted pi/2 radians.

That is the ONLY phase information I can glean. It is fairly useless knowledge. It says NOTHING about the delay of the current through the coil including a loading coil that is functioning partially as an antenna.

It doesn't matter Roy, I am just talking about a transmission line whose
condx are set up for a voltage standing wave whose values are zero at the
endpoints. remove the short circuit and make it open and you have a
different standing wave shifted pi/2. That is not the point. I am talking
about "a" standing wave and its lack of relationship to delay through a
coil. We can take the quiz on the differences between open and short
circuited xmission line standing waves later although I will not bother
since it is quite fundamental and unnecessary.

After the bruising testimony of your own measurement, you certainly
needed some victory. :-)

Um, does your personal tragedy lead anywhere? I'm not interested in
reading the repetition of "impossible" being cried into your pillow.
Certainly you still have time to rummage up something lost in the
folds and recesses of that MENSA approved mind. Tom and your results
could have happened with Arthur's principle of antigravity, couldn't
it? That doesn't need anymore proof than your plaintive wails into
the cold void of an uncaring universe.

Roy and the others call this "last man standing." Myself, I would say
it is what the law calls an attractive nuisance - and barring
correspondence with any technical content, it is far more fun. Your
legacy is that for many, this is your ONLY exposure.

You want to be last? Hug Tom and pull the pin!

Or, to sum that up in a nut shell, "Does everyone here know we can reverse the leads on our SWR meter (input goes to output--output goes to input) and the fwd/ref switch will just work "backwards." (but, readings should remain the same.)

Indeed, an excellent way to check homebuilt SWR bridges and make sure they are "balanced."

This isn't quite correct. A standing wave is the result of isn't the sum of traveling waves. It's a description of the envelope of the current distribution that sum produces. The sum of the traveling wave voltages is the total voltage. The sum of the traveling wave currents is the total current. It's relatively to measure the total voltage or current at any point and, if you measure them at enough points you can use the measurements to draw a graph of the standing wave.

> A DIRECTIONAL
> volt meter or ammeter will measure only the traveling wave within the
> design direction, but can not distinguish between components from
> multiple reflections that might combine.

Yes.

> A directional voltmeter or ammeter will measure the same voltage or
> current no matter where it is placed in the transmission line under
> steady state conditions, assuming no resistive losses in the
> transmission line.

That's only partially true. Both the traveling waves and the total voltage and current have not only magnitude but also phase. A directional coupler can measure both the magnitude and phase of the traveling waves (but some directional detectors like a Bird wattmeter indirectly measure only the amplitude). Traveling wave measurements at different points along a lossless line will have the same magnitude, but different phases. So the voltages or currents at those points aren't the same.

I use a measuring tape for that, so there is no
problem. But if I recall correctly, your definition
of 90 degress is not amenable to the use of
measuring tapes.

> If the phase shift end-to-end is 180 degrees, the

Everyone thinks they are full of "common sense" and
that few others are. Science is not advanced by claiming
common sense.

If you do not have articulatable rules, then you do
not even have a hypothesis, much less a theory.

> If a dipole is 130 feet, it is 1/2WL on ~3.6 MHz.
> If the antenna is 403 feet long, it is 1.5WL on
> ~3.6 MHz. Why do you have a problem telling the
> difference between a 130 foot dipole and a 403
> foot dipole?

No problem. But I am allowed to use a measuring
tape to answer that question.

And if you wrote a rule using measuring tapes for
this 90 degree stuff, I would have no trouble with it
either.

But if the best you can do is claim "common
sense", you can be sure that my "common
sense" will arrive at different answers than yours.

So let us in on your strategy, Roy. You freely admit
that the phase of standing-wave current is unchanging
yet you use exactly that current to "measure" the phase
shift through a loading coil. You admit that your methods
are meaningless but you continue to stand by them. Please
explain your agenda. Are you trying to establish a new
religion or what?

The internet is not for children. If you don't have a decent spam
filter on your email--shame on you. If you don't have a decent spam
filter on your newsreader, shame on you.

If you think your definition of a troll is everyone elses' think
again--some define troll as, "Does not agree with me."

Go figure ...

Personal advice from the anonymous. More irony than value there; and
you could as easily be Ossama Bin Forgotten wishing us Deadly
Christmas and a Satan hugging New Year muttered under your beard.

Others might teach me about manners, but they haven't weighed in, have
they? They would put the substance of their names behind their
lesson, and they would have a reputation of civil discourse in
contrast to mine. It's happened before, but you and Cecil aren't
standing in that long line.

>Not only is this boring, it is plain disgusting. My gawd man, step back
>for a moment or two and get a hold of yourself.

As for being bored? This has been a grind, certainly; 600+ postings
informs us all of that! [Talk about the bleeding obvious. Reggie
would have his thumb in your eye.] You getting bored, however, speaks
only to your own veiled hedonism. Your moral balance is seized with
the rust of anonymity.

Want to move away from personalities? Try participating with
technical comments or providing data. Cecil abandoned it with his
claim of being hounded with 20 questions. How many more than 20
questions litter this thread from him? How much data arrived from
those 20 questions? Did you find yourself informed during that
interchange? Did none of them raise your interest to engage your own
participation? Was there anything in their relation to the
measurement that revealed success or failure? Did you find anything
"personal" in their revelation? Did you laud or challenge that
enquiry or its analysis? Did it elicit any questions? Frankly, you
show very little interest in these topics except when the
entertainment becomes a bit too purple. It has, no doubt about it;
but you don't even have the critic's qualifications to do anything
more than phone in a vote to American Idol and hope Simon doesn't pick
up the line.

You chose to respond to the comedy, and stood silent in the exchange
of idea and information. No, I don't see any lesson offered here by
you that you don't need learning first.

This last paragraph gets to the heart of the issue. One concept of a
transmission line is that the traveling wave is always in phase in the
sense that the power contained in the wave is the envelope that is
properly considered. In this concept, the voltage and current are
always in phase, MUST be in phase. This power wave may be split as at a
reflection point, but the components will never be out of phase because

the power calculation would be incorrect.if it was out of phase.

The second concept of a transmission line allows the traveling wave to have voltage out of phase with the current. Here the power can be all stored in either the current (magnetic) field or the voltage field, depending upon the phase of the traveling wave. The character of the wave changes (so to speak) depending upon location and phase.

If the transmission line is terminated with a resistance, the constantly-in-phase traveling wave concept provides the theoretical basis for calculation of the reflection coefficient.

I think that consideration of the conditions at the end of a transmission line are a good place to examine as we try to get some experimental guidance.

If the transmission line is shorted (or open), it is hard to visualize how the voltage (or current) could flow to the short (or open) and then just disappear. Does the wave cancel (or disappear) at the intersection (open end)? Do the waves pass through each other, so we see only the vector sum? Do the waves "pile up" at the open end, but not at the short?

The constantly-in-phase traveling wave concept requires the difficult-to-believe observation that a directional ammeter placed very near the end of an open transmission line will read the same current as if it were placed at the source end. Perhaps someone can perform that experiment some day, but I can not imagine how it can be done without placing a load on the line, thus invalidating the initial assumptions.

Hi Mac,

I read the headers in posts (they are typically hidden to the casual
reader). I can also cross reference the IP address in that header to
a City and State. Our student's location is some 60 miles south of
where you sometimes post. Let's call it a SWAG that he is attending
the University where you are. ;-)

I cannot say that I have been a complete or reliable source, but we've
managed to cover some of the fundamental concerns and it didn't seem
appropriate to finish his semester project for him.

Sorry, I can't make much sense out of that. Voltage and current don't
have to be in phase in order for power (energy flow) to be present. But
I'd rather not introduce power into the discussion. It's not necessary
in explaining what I've presented, and brings the opportunity for a
whole new level of misunderstanding and folklore.

> The second concept of a transmission line allows the traveling wave to

The ratio of V to I of the traveling wave is the Z0 of the line. In a
lossless line, this is a pure resistance, so the V and I of traveling
waves are in phase.

> If the transmission line is terminated with a resistance, the
> constantly-in-phase traveling wave concept provides the theoretical
> basis for calculation of the reflection coefficient.

The reflection coefficient can easily be calculated regardless of
whether or not the load impedance is resistive or reactive. The load
impedance doesn't have any effect on the relationship between V and I
traveling waves going the same direction; it affects only the amplitude
and phase relationship between waves going in opposite directions.

> not at the short?

The voltage and current at any point along a line, including the ends, equals the sum of the forward and reflected voltage or current waves at that point. At a short circuit, the voltage is zero. This means that the sum of the forward and reverse waves at that point is zero, which in turn means that the two are equal in magnitude and out of phase. (Another way of saying this is that the voltage reflection coefficient is -1 at that point.) At an open circuit, the current is zero. I'll leave it as an exercise to the reader to figure out what this means about the relationship between the forward and reverse traveling current waves.

I am not in this field, I have a bachelors in electronic engineering--from decades ago, but never used it, monetary avenues in other directions lead me far afield ...

My most recent degree is in in software engineering, and this is where I have worked the last few of decades+ ... I would assist, but like you, I am a student--of the hobby--and here for my own enjoyment/recreation/etc. ...

However, I would suspect J. Mc Laughlins' offer is real and quite WORTHWHILE (in the above post)--if I were you, I'd take him up on it, you will do as you please.

But, I'd say Mc Laughlin is your man ...

Warm regards,
best of luck,
JS

I do not understand why people will not accept that, when one connects a length of transmission line of Zo1 to another length of transmission line with Zo2, there can/will be a phase change at the discontinuity.

If there is a phase change on the Zo1 line by itself when the discontinuity is 0 + j0 impedance (short) or 0 +j0 conductance (open), shouldn't there be a phase shift between 0 and pi/2 when the impedance (or as you say, "impedor") is added somewhere in between, i.e. when connecting the line of Zo2, such as -j567 ohms at the electrical degree point of the termination?

It is partially understood in terms of a lumped component of -j567 but that model describes the mismatch at the discontinuity only. It must be corrected at the system level to also accouint for the known 10 degree additional transmission line contribution of the 100 ohm line.

It is not the same concept as 2 independent open circuited transmission lines connected in series. That situation is impossible because you cannot get away from the phase change at the discontinuity. The 600 ohm line cannot be "open" when there is a mismatch of another line whose Zo is other than 600 ohms connected to it in series.

Thus, 3 phase shifts must be accounted for:

1. 600 ohm line
2. "Impedor" phase shift at discontinuity
4. 100 ohm line

Dear Sirs or madams,

How are u today ?

Now let us take this opportunity to introduce ourselves,Qifei electronic, as one of professional manufacturer in the field of TV reception system such as MMDS downconverter , C/KU-band LNB/LNBF and so on .We are loacted at southeast of China adjencent Shanghai to Nanjing(the heart of GoldenYangtze River in China). Nowadays ,we have about 50 employees and 100000 pcs per month sold out both domestic and abroad market. For a full company profile I sincerely invite you to visit our website as the followings: http://www.zjqifei.com/english/company.asp PC:We also attech our catalogue and price list to u for your reference.

Should u interest any items ,please let us know and the exact and competitive quotation upon your specific model ,quantity and require.

We are looking forward to hearing from u and will carefully consider any proposals likely to lead to business between us.

Best regards,

Eason

> placing a load on the line, thus invalidating the initial assumptions.

The experiment will show the expected result but will
not help understand why. For that, examination of
the measurements and arithmetic performed by
a directional ammeter is useful.

Below, all voltages and currents are instantaneous.

Total voltage, Vt = Vf + Vr
Total current, It = If - Ir

Vf = If * Z0
Vr = Ir * Z0

Substituting....

Vt = (If + Ir) * Z0
Ir = Vt/Z0 - If

If = It + Ir
If = It + (Vt/Z0 - If)
If = (It + Vt/Z0)/2

Similarly, Ir = (It - Vt/Z0)/2

The directional ammeter measures instantaneous
Vt and It, does the above arithmetic and presents
If. A directional ammeter that presents a single
number rather than the time varying If has probably
converted the instantaneous values to RMS.

Examing It and Vt at various points on the line
and doing the above arithmetic will reveal why
the same value for If is obtained everywhere.

Directional wattmeters are more common
than directional ammeters. A directional
wattmeter does the above arithmetic then
squares If, multiplies by Z0 and presents
the results in watts.

All this from just measuring Vt and It.

There is no evidence that I have performed the experiment.
The need for current probes probably means that I will not
be doing so, though you never know. Rest assured that
should I do so, results will be published.

> and know that I am right, you try to tuck your tail
> and run.

Ahhh, your favourite accusation. You play the game
of last man standing, and when everyone has left
the field (in this case because you had nothing
further technical to add), you convince yourself
that it is because you must be right, and they
must know it. I can't decide if this logic is
more amusing or sad.

Now if you want to recover, make some better
attempts to write the rule. Look back through
the posts for your sentences that begin with
"Can we agree that", or some such. These
were your attempts at a rule. Complete them
to the point that we agree that they are self
consistent and accurately convey your
definition and we will have gotten somewhere.

Your later attempts, which amount to "I
know it when I see it", were not nearly as
good as your earlier ones.

What is it that you need a rule for? Is it the
electrical length of a stub?

The stub is electrically half as long as the phase
shift undergone by the reflected wave during its
round trip to the open or shorted end and
back to the feedpoint.

If that phase shift in a dual-Z0 stub is the same
as the phase shift in a single-Z0 stub at the same
frequency, the two stubs are the same electrical
length at that frequency.

This argument does seem to have a certain attractiveness.

> It is partially understood in terms of a lumped component of -j567 but that
> model describes the mismatch at the discontinuity only. It must be corrected
> at the system level to also accouint for the known 10 degree additional
> transmission line contribution of the 100 ohm line.

It seems to me that if connecting a -j567 impedance
produces a certain response, it should not matter how
that -j567 impedance is produced. Consider the following
cases:

- produce the -j567 with a lumped capacitor
- produce the -j567 with 10 degrees of 100 ohm line
- produce the -j567 with 46.6 degrees of 600 ohm line

The claim appears to be that despite the 43.4 degrees
of 600 ohm line being terminated in the exact same
-j567 impedance in all cases, the phase shift
experienced at the interface is different in each
case.

Does this really make sense?

They are terminated in the same value of impedance
but they are not terminated in identical impedances.
Please see the IEEE Dictionary for the three different
definitions of impedance. Each case involves a different
reflection coefficient at the -j567 point.
(I added a number to each case above.)

(1) involves an *impedor* with a reflection coefficient
of 1.0 at -93.2 degrees when connected to the 600
ohm line. The reflected wave at the feedpoint lags
the forward wave by 43.4 + 93.2 + 43.4 = 180 degrees.
The impedance is a real impedor, not a virtual impedance.

(2) involves an impedance discontinuity with a
reflection coefficient of -0.7143. With 10 degrees
of 100 ohm line, the reflected wave lags the forward
wave by 2(43.4 + 36.6 + 10) = 180 degrees. The phase
shift at the discontinuity is 36.6 degrees each way.
The impedance is caused by superposition of component
waves at the impedance discontinuity.

(3) with 46.6 degrees of 600 ohm line, the reflected
wave lags the forward wave by 2(43.4 + 0 + 46.6) = 180
degrees. The phase shift at the 600 to 600 ohm junction
is zero. The reflection coefficient at the 600 to 600
ohm junction is 0, different from (1) and (2) above.
The impedance is completely virtual and thus cannot
cause anything.

Roy Lewallen wrote:
> This isn't quite correct. A standing wave isn't the sum of traveling
> waves. It's a description of the envelope of the current distribution
> that sum produces. . .

Look at this standing wave:

http://www.chemmybear.com/standing.html

The equation for that standing wave is:

Ex = E*e^j(wt-Bz) + E'*e^j(wt+Bz) [see quote below]

At one time in the cycle, the standing wave equals zero
all up and down the line.

A STANDING WAVE *IS* THE SUM OF TRAVELING WAVES.

On page 285 of "Fields and Waves in Modern Radio",
2nd edition, by Ramo and Whinnery, it gives the
equations for the forward wave, the reflected wave,
and the standing wave. Begin quote:

Incident Wave ---> E*e^j(wt-Bz)

Reflected Wave <--- -E*e^j(wt+Bz)

If Ex = 0 at z = 0 for all values of time, E' = -E.

[Standing Wave equation]
Ex = E*e^j(wt-Bz) + E'*e^j(wt+Bz) = -2jE*sin(Bz e^jwt)

[Standing wave envelope equation on page 42]
V = -2jV1*sin(Bz)

End quote:

The standing wave equation is simply the sum of the
traveling wave equations.

I don't think that the directional ammeter reads instantaneous Vt and It. The circuits I am thinking of sample a length of line (NOT A POINT) so the sample records average voltage (or current) from a period of time.

If I understand the methodology of the directional ammeter correctly, it extracts energy from the wave from both magnetic (current) and voltage components. If the components are in phase, they add, and that only occurs with the wave going in the design direction. Yes, this is a reading of power, not voltage or current individually. Current and voltage are related by the Zo of the transmission line, so if we know current, we also know voltage, and visa versa.

Agreed?

Only partly. If you look at the element on an instrument
like a Bird 43, you will find that it is both capacitively
and inductively coupled to the line. The capactive
coupling is sensitive to the total voltage on the line
at the point of the element, while the inductive coupling
is sensitive to the total current in the line.

The subtraction (or addition) is done in the element
where the voltage sample and the current sample
(scaled by Z0) are subtracted before being applied
to the diode. The output of the diode is the
rectified instantaneous difference of the voltage and
scaled current from the equations originally provided.
This is fed to an average responding meter which has
a scale marked to show (Vf**2)/Z0 (i.e. power).

You are correct that the element does not sample
at a point, but rather over the width of the coupling
element. This is done because of design
limitations and is one of the sources for error in the
instrument, though small if the wavelength is long
compared to the element.

There are many ways to obtain the instaneous
voltage and current for the subtraction (or addition).
Some designs measure the voltage by using
an electrical connection to the line, so these are
essentially measuring at a point. Other designs
measure the current by detecting the voltage
drop across a resistor in series with the line.

Diagrams of the internals of the Bird 43 element
are available in the Operations Manual here:
http://www.bird-electronic.com/products/product.aspx?id=81

Here are the associated equations:

Vz = V*e^-jBz + V'*e^+jBz

Iz*Z0 = V*e^-jBz - V'*e^+jBz

Current is sampled in such a way as to perform
the multiplication by Z0. That's where the calibration
to Z0 comes in.

If one adds the two equations (samples) the reflected
terms drop out and the result is a voltage proportional
to the forward wave.

If one subtracts the two equations (samples) the
forward terms drop out and the result is a voltage
proportional to the reflected wave.

Continuing: The phase of the standing-wave current
in a 1/4WL stub is constant from feedpoint to tip.
However, two directional couplers, one placed at the
1/3 point and the other placed at the 2/3 point
would allow one to see the 30 degree phase shift in
the traveling-waves at the points before diode
rectification takes place.

Another common directional wattmeter circuit is the Bruene type circuit. This uses an ordinary current transformer to get the current sample and a direct connection for the voltage sample. The voltage sample is reduced to the correct proportional value via a transformer or capacitive voltage divider. It shouldn't be hard to find a diagram of one on the web.

Roy Lewallen, W7EL

The article at http://www.vk1od.net/VSWR/VSWRMeter.htm includes a simple
circuit analysis of the Breune design and some comment on the application
of the instrument.

Many simple reflectometer designs do indeed sample the line over a short length of line, and that short length may be 100mm or more.

Ideally, they would take the sample at a point. (Since a point has zero length, I can't quickly think of a sampling technique that truly takes a point sample.)

Although sampling over a non-zero length limits their accuracy somewhat, if that length is kept sufficiently short, they are still able to provide sufficiently accurate measurements.

The voltage sample is easy... measure the voltage using an infinitely
thin probe.

The current sample is measured in a similar way by measuring the
magnetic field over a infinitely small segment of the conductor. There
are sensitivity issues or bandwidth issues, but there are lots of very,
very small magnetic field probe schemes around.

If one says, "point sample" == "less than 1/1000 wavelength), I think
it's actually pretty straight forward, certainly for 100 MHz or less.

(3mm is 1/1000 lambda).

The question was excellent. 'Impedance discontinuity points' is nonsense.

> How many nanoseconds does it take for a signal to travel
> through a dimensionless point???? Well, let's see. What
> is the speed of light multiplied by zero? Hmmmm, that's
> a really tough one.

The hard part would be inverting zero sec^-1 in order to get units of
time. :-)

An excellent point, Keith. And applications for it abound.

Problem is that it conflicts with the predictions made by the power propagation model. (The politically correct name is the Joules/sec propagation model.) That model shows that only a single reflection of power is needed to explain the whole thing. Of course in some cases the wave of power has to figure out how to turn around and go back the other direction after it's been cancelled in order to conserve energy. (A problem it wouldn't have to solve had it not violated it in the first place.) Admittedly, some of the details have yet to be worked out. :-)

It is common practice during an analysis to consider
the impedance discontinuity where Z0 changes to be point
connections at a plane. All of my technical books draw
the connections that way. None of them attempt to
treat the connection as anything other than points.
If you choose to analyze what happens at a 1 mm drop
of solder, be my guest.

Doesn't take current sample

Probe is of finite size (albeit small fraction of lambda in most cases)

The difficulty of making accurate RF current measurements at a point is why things like slotted lines were invented. You can measure voltage at a series of points and calculate what the current *must* be.

Thanks Richard and Jim,

I mean't literally a point sample, and I doubt that we can manufacture a probe for either voltage or current that has zero dimensions (ie is influenced ONLY by conditions at a point of no physical size.).

I go on to say (if you read on) in different words that notwithstanding that, practical probes can be made that give acceptable accuracy.

They unsaid key thing is that these probes do not depend on averaging over a length of line (as Roger suggested), that is actually a defect that limits their usable upper frequency.

Owen

Wow Jim, you need to repeat Fields and Waves 310. :-)
You have misunderstood virtually every principle
of the wave reflection model.

I wouldn't presume to take credit for any of the above. I learned it
on r.r.a.a. from someone who I think needs to take Fields and Waves 1.
:-)

Hi Jim,

Never needed to with a slotted line.

>Probe is of finite size (albeit small fraction of lambda in most cases)

And the time to measure anything is finite too.

>The difficulty of making accurate RF current measurements at a point is
>why things like slotted lines were invented. You can measure voltage at
>a series of points and calculate what the current *must* be.

At worst, only three points, and generally for SWRs folks here would
agree were astronomical (and incalculable, but I could measure them
anyway).

With four fixed points (nominally eighth wave, but a range of
frequencies can be accommodated), I could determine the complex
impedance of any load. [re. "Microwave Measurements," Ginzton, Sec.
5.12] There are a myriad of other slotted line techniques, but I will
leave them for a suitable occasion.

I have never had to consider what the current *must* be - an
unnecessary elaboration.

If you are talking about me, you have either misunderstood
what I said or you enjoy bearing false witness. Here's a quote
from my 2005 magazine article at:

http://www.w5dxp.com/energy.htm

"The author has endeavored to satisfy the purists in this
series of articles. The term "power flow" has been avoided
in favor of "energy flow". Power is a measure of that energy
flow per unit time through a plane. Likewise, the EM fields
in the waves do the interfering. Powers, treated as scalars,
are incapable of interference. Any sign associated with a power
in this paper is the sign of the cosine of the phase angle
between two voltage phasors."

Also, here is an EXCEL spreadsheet version of what happens
during the transient buildup to steady-state.

http://www.w5dxp.com/1secsgat.gif

Do you really consider 30 iterations to be only a single
reflection?

>influenced ONLY by conditions at a point of no physical size.).

Hi Owen,

I would say that is arguable given my exposure to research in
Nanotechnology. I've seen one molecule probes (illustrated actually,
by microscopes that do enjoy vastly higher resolutions than were state
of the art 10 years ago; and they can image complex atoms and small
molecules).

These scales are commonly referred to as 1D, or quantum dots. Now,
given a measurement must be made, it demands a probe. Further, given
a quantum dot sized probe, it necessarily describes the smallest size
for which any smaller size yields no more information.

The practicality of it is that this quantum dot would have to reside
at the end of a very thin lead. A carbon nanotube so qualifies, and
they can be grown to considerable length (for this field), and they
themselves occupy no more than 1nM diameter (for a single walled
construction which is not terribly difficult to obtain).

In the practical field of RF, I seriously doubt such a probe/lead
combination would perturb a slotted line. In fact, their influence
would be lost in the decimals far to the right of the accuracy of the
line's construction. Or, I could easily imagine that most computers
would suffer rounding errors long before the probe/lead's influence
could be calculated if the line were perfect.

Yes, for the absolutist (no speaking of you Owen), a probe could never
be small enough, but if it were smaller it would be impossible to
obtain a reading. Sort of self-extermination of the absolutist
argument.

Richard:

In my course of study, I was forced to take a class in human psychology--I hated it--its' use I could not fathom, to one engaged in the technical aspects of "the real world" it seemed a waste.

However, that class was all about running into the likes of you.

You are an actor on a stage, yet we all wish to view NO performance. You are a writer, in your imagination--yet we have no interest in your book. You are all important--to yourself, but you have NO importance to me.

You are a spoiled child who will even accept "negative attention" as opposed to "no attention at all"--and in all actuality--that is what you truly deserve.

You are a mess man, get a hold of yourself ... anyone who would even lend a hand in your support is an idiot--OWN IT MAN! Only an idiot can befriend you at the present time--grow up ...

Now,
3's :-)

I may have misspoken. Once you get to -j567 at the discontinuity (travelling 10 degrees along the 100 ohm line), now you interface with the 600 ohm line. At that point you have to normalize the -j567 ohms to -j(567/600) = -j0.945 on the smith chart (you normalize to Zo for it to calculate properly). This abrupt switch increases the angle from 10 degrees to arctan (0.945)) or 43 degrees. I think the effect to look for is that the abrupt impedance change when Zo changes. A lumped component is not enough to make the model correct. Comments welcome.

Hi Dan,

It works both ways. However, lines can appear to be equivalent to lumped components until you, say, double the frequency. The two models clearly diverge. Where you could place a series resonant lumped circuit in place of a resonant line (or versa vice) at a fundamental frequency, the lumped series circuit would rarely demonstrate parallel resonance at twice that frequency, but the line would.

But it appears the model hasn't been constrained to less than an octave bandwidth - until after Keith submitted the winning ticket to the lottery commission. Cecil's lotteries are like that. To date (more than 12 years now) you are the only winner, and I haven't seen your prize awarded yet.

Agreed; we're discussing principles here, and the issue of single-point sampling is mostly a practical one.

In principle, we can always choose a method of sampling that doesn't require a finite length of line. Within the limits of our skill and imagination, we can also make the current and voltage pickups physically smaller, so that they occupy less length along the line. Or if skill and imagination fail, we can shift the whole discussion to longer and longer wavelengths, to make the error as small as we like. It may not be practical, but no general principles are being broken.

The issue of single-point sampling is interesting in its own right, but in this much wider discussion it is only a minor detail. In order to move on with the wider discussion, let's agree to assume that single-point sampling always *can* be achieved, within the accuracy that we require.

>
>If one says, "point sample" == "less than 1/1000 wavelength), I think
>it's actually pretty straight forward, certainly for 100 MHz or less.
>(3mm is 1/1000 lambda).

Even for practical instruments, this particular source of error is usually quite small. At any one frequency, it is always possible to null the bridge in the reverse direction, so that the voltage and current samples (as described by Cecil) will cancel. How well the cancellation holds over a wider frequency band will depend on the choice of bridge

circuit and the way it is constructed.

Hello,

Would like to compare link budget between
portable-radio with typical small rubber whip antenna and
vehicular-radio with 1/4-wave or 5/8 antenna or vertical dipole on the
roof

Gain difference between vertical ground plane and dipole is about 2dB.

What I'm looking for is the gain difference between

portable whip
1/4-wave on car roof
5/8 on car roof
Vertical dipole

Does anybody have more info?

Thanks in advance

Pierre
ON7CIP

It's a NO-NO. Don't call it "antenna".

>1/4-wave on car roof

THE standard.

>5/8 on car roof

Definitely bad on 2 meters.
Whip is elastic and moves and wiggles and causes additional QSB.

>Vertical dipole

Not on a car roof.

>
>Does anybody have more info?
You do. What's your operating frequency range.
Why do you keep it top secret?

Exactly. Plot -j567/100 and -j567/600 on a Smith Chart and
read the phase shift directly from the wavelength scale
around the outside of the chart.

Well, not exactly directly. One must multiply the
delta-wavelength by 360 degrees to get the phase
shift. If the angle of reflection coefficient
degree scale is used, it must be divided by two
to get the actual phase shift.

3120. Wave Reflection model

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-11 15:29:21 UTC
From: Cecil Moore <nospam@w5dxp.com>
Message-ID: <l1y7j.52861$eY.12505@newssvr13.news.prodigy.net>
Source record: 31677

I've been reviewing my 1950s college textbooks to
see where my concepts came from. Here's a couple
of example quotes:

"Transmission Lines and Networks", Walter C. Johnson,
(c) 1950.

"... when the load reflects part of the incident energy,
it is found that the rms voltage and current vary almost
periodically along the line. This *effect* is *caused*
by the *interference* between the incident and reflected
waves, and the *resultant* variation is called a standing
wave."

The idea that interference *causes* effects (such as
standing waves) was not originated by me.

"Fields and Waves in Modern Radio", Ramo and Whinnery,
(c) 1944, 1953

"... energy cannot pass the perfect conductor ... Hence
all *energy brought* by the incident wave must be returned
in a reflected wave."

The idea that waves *bring* energy and that there is actual
energy in a reflected wave was not originated by me.

These concepts were probably around before I was born.

The limits of a field of equilibrium can be seen as a distorted bubble
the shape of which is governed by the laws of partial pressures.
A galaxy can be seen as a cluster of such gravitational bubbles
where all are in a state of equilibrium as is the cluster itself. All
of which
are bound by a nuetral force bonded skin or surface such as with H2O
upon which can carry small forces such as an insect e.t.c..
These surfaces create clusters of gravitational force that can only
be broken in shear because of the laws of partial pressure where they
can reform in equilibrium or unite with associated gravitational
fields
in a ever expanding form.(two forces in compression create a shear
line at 45 degrees to the force axis)
Since a cluster is finite as with a bubble bath where all neutral
surface
cling to each other then the extremes of these surface which are
bound by a common neutral bound 'skin' must be a volume where
nothing exists. When the cluster expandes into a new partial pressure
zone a new boundary or miniscus is formed to bond the innards in a
state of equilibrium. Therefore all movement cannot exist without
rotation..
Food for thought.
I provided this posting because only outside the subject of antennas
can this group continue to exist in a cordial manner.
Will this stop disagreement? I doubt it since as we all became
pseudo experts in radio transmission by the same token we can become
pseudo experts in physics. Einstein move over!

Isn't that like lossless wires, perfect grounds, and other such?

The conditions that cause an object to slow and stop in real life are the proof of the law. To the contrary, it proves Newton correct. The forces act just as they should.

3127. Creating Large Ferrite Antenna tuned to 457khz range?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-11 17:18:46 UTC
From: cmor <alpinedescents@gmail.com>
Message-ID: <f2d94a6f-5d4e-444b-a945-becdacb48e30@i29g2000prf.googlegroups.com>
Source record: 31684

I'm trying to create a largish ferrite receiver antenna tuned
exclusively to the 457khz range. I was going to get the ferrite rod
from here:

http://www.stormwise.com/page26.htm

As I only need the single frequency I was wondering if it was more
effective to make a self-resonant antenna?, or does a capacitor not
decrease quality of the single?

Secondlly, I have very little experience in the radio world, and was
considering following am radio plans similar to this to attach my
antenna to:
http://www.stormwise.com/page56.htm

Just swapping the variable capacitor for a fixed one tuned to my
frequency.

Is this the optimal way to get the strongest signal? Can anyone point
me in a direction to get more information on how to build such a
receiver? Most important is the range of the antenna in picking up
very weak signals.

Thanks,
Chris

Are you trying to build a better avalanche receiver or what? The
trancievers available today seem to be pretty good.

What specific kind of signals are you trying to pick up, and what is it that will prevent you from hearing them? That is, if the signals are buried in atmospheric noise, a more "sensitive" antenna that also picks up more noise as well as more signal isn't going to help the signal-to-noise ratio. For that, you may need to use some additional knowledge about the signal that you can use to differentiate it from the noise. At 457kHz, atmospheric noise is very high amplitude, and it doesn't take much of an antenna plus receiver to get all the signal that will do you any good.

On the other hand, if the thing that keeps you from hearing the desired signal is an interfering signal, the null of a loop (or ferrite rod) antenna can be used to get rid of that signal that comes from one direction (which lets you listen more easily to the desired signal, provided your desired signal isn't coming from the same direction).

Cheers,
Tom

Hi Cecil -

Yes, I'm very familiar with that article. You've already posted a
link to it dozens of times on this newsgroup. It very clearly
illustrates exactly those thing which I may have somewhat more
'colorfully' restated above, and more. It includes equations with
variables for forward and reflected power all throughout, a reference
to a supposed "4th mechanism of reflection" (that's the magical way in
which waves of power and energy change direction), and illustrations

with arrows named Pref showing how power is reflected at impedance discontinuities.

Back when our corresponence was more cordial, I advised you not to write those things. And now you'd like to deny having done it; all the while portraying me as a liar. You're beautiful, man.

It must have taken great courage to admit that. Perhaps there's some consolation in the fact that you can still take credit for originating the idea that interference causes waves to reflect. :-)

> The idea that waves *bring* energy and that there is actual
> energy in a reflected wave was not originated by me.

Believe it or not, even prior to the advent of radio it was presumed that waves transport energy, from the Sun to the Earth for example. Still, it must be a humbling concession to make. :-)

> reflected power all throughout,

Yes, forward and reflected power measured at a *FIXED* measurement
point. There is no "power flow" anywhere in my article. Energy
does the flowing. Power is the measurement at a *FIXED* measurement
point of that energy flow past that *FIXED* point. Did you note
the use of the word, "FIXED"?

Even though all my references, including the IEEE Dictionary
allow for "power flow", I avoided it in my article as a favor
to you.

> a reference to a supposed "4th mechanism
> of reflection" (that's the magical way in which waves of power and
> energy change direction),

Yes, that may be somewhat original and therefore frightening
for you. Galileo would have scared you to death. If, as Walter
C. Johnson says, interference can *cause* standing waves, it
can probably also cause reflections at an impedance discontinuity
through wave cancellation. You are going to have to do more
than wave your hands to prove otherwise. Not refusing to
answer my questions about my examples would be a good start.

Remember your absolute refusal to compute the total joules/sec
after the first internal reflection arrived at the thin-film
anti-reflective coating in my example? When you learn how to
properly manage irradiance, get back to us.

> and illustrations with arrows named Pref
> showing how power is reflected at impedance discontinuities.

No! No! No! Power is NOT reflected at an impedance discontinuity.
Those are Poynting vectors. Energy is reflected and that reflected
energy is measured and called "reflected power". Reflected power
is not moving. You continue to get it wrong. The reflected power
is acutally reflected energy measured flowing past a *FIXED* point
near the impedance discontinuity. There are joules in the reflected
wave. The joules in the reflected wave are measured flowing past
a *FIXED* measurement point. But, of course, I have explained
all of this to you before yet you continue bear false witness

after all these years.

> Back when our corresponence was more cordial, I advised you not to write
> those things. And now you'd like to deny having done it; all the while
> portraying me as a liar. You're beautiful, man.

I changed my article just to make you happy. You obviously
have misunderstood, either through lack of processing power,
ignorance, or deliberately. I would guess it is deliberate.

I have *never* said I was uttering anything original. I
am on record for learning all this in college 50 years
ago. Any prudent physicist would be forced by reality to
admit that the principle of conservation principle is valid
and the wave reflection model is valid. If you accept the
validity of those two models, you cannot help but realize
that wave cancellation results in reflections.

If two coherent waves are canceled in one direction in a
transmission line, where do their energy components go?
It's a no-brainer. There is only one other direction
available.

I have never asserted that anything I have presented was
original. I have said I learned it all in college 50 years ago.

Some have asserted that reflected waves must not contain any
energy because they don't care where the energy goes. Such are
the delusions of grandeur exhibited by some on this newsgroup.

To repeat my posting of Dec. 8:

This would be funny if it weren't sad. This newsgroup is one of the few places I can think of where the silly statement I posted about moving bodies and friction would be taken seriously. But it's really no surprise, since it's much less unreasonable than the imaginative alternative theories which are seriously presented, and just as seriously argued, here daily.

My postulate about objects in motion was a parody of Cecil's rejection of theoretical cases on the basis that they can't exist in practice, my intent being to show how such a rejection leads to incorrect results. But I see it's drawing the same serious response as Cecil's and Art's postings. All that's missing is one of Richard's quotes from Terman and support from Derek.

Roy, once again you distort what I have said.
I did NOT reject any theoretical cases. I said
I personally don't have time to consider those
cases as my daughter is facing emergency surgery
in New York state and I am standing by to hop a
plane during the Christmas season rush.

If you know more about my personal time than I do,
please let me know exactly how you accomplish that
feat. If your argument is that gurus know everything,
I will certainly understand. You have used that
argument before.

I'll tell you what would be funny if it weren't sad. You present yourself as some omniscient guru on this newsgroup yet you recently showed your absolute ignorance of standing waves and the math behind that subject.

Most of the knowledgeable people on this newsgroup now know that, as far as standing waves go, you are just a flimflam man. I am amazed that you have the balls to post anything else after that fiasco.

As another poster said, there is very high noise at this frequency. The way this radio works is to use the coil as both an antenna and the resonating inductance in the tuned circuit. I have found that, in high noise applications like this, often the best way to get a clear signal is to off-tune the receiving antenna, for example, tuning the receiving circuit to the frequency you need but using a shorter antenna. A 40m antenna often works well for receiving 80m and 160m stations without all the noise. However, you cannot employ such a method with this radio. The radio does look interesting from a hobbyist point of view though, and a good way to sell large ferrite rods :-)

Do you mean you can get a better signal/noise ratio with a 40 m antenna on 80 or 160 than with a half wave 80 or 160 meter antenna? If so, what do you suppose the mechanism is by which the shorter antenna distinguishes between signal and noise?

I've seen cases where a receiver designed for use with a small whip antenna became overloaded when connected to a decent antenna. Adding attenuation or using a shorter antenna improved the S/N ratio because a lot of the noise was due to intermod from the receiver overloading. I've never seen this with a decent receiver, however.

I follow the arithmetic, and it still has a certain attractiveness
but how can it make such a difference how the -j567 is produced.

What if you were offerred 3 black boxes, each labelled -j567?
Would it make much difference what was in them?
How does one compute the phase shift at the terminals?

> The impedance is completely virtual and thus cannot

> cause anything.

I see how you have done the arithmetic, and if I
understand correctly, you would claim these are
all systems with 90 "electical degrees".

What about the following...

Open circuit 46.6 degrees of 600 ohm line attached
to 80 degrees of 100 ohm line. The drive point impedance
will be 0 ohms. And the impedance at the junction will
be the same -j567. Using your arithmetic, there is
90-46.6-80 -> -36.6 degrees of phase shift at the
junction. The physical length is 126.6 degrees
while the system is 90 "electrical degrees".

Is the definition of a system with 90 "electrical degrees"
becoming any system where the drive point impedance
has no reactive component?

Did Johnson really say "almost periodically"?
Pretty close to periodic, but not quite? Hmmmm!

I suppose it just shows that even the best write
with a bit of laxness now and then.

Short quotations without the context are so unfair.

Yes, Johnson said that, but it's due to being precise rather than lax. Much of the following sections deals with lines having loss, so his statement is quite apparently intended to include them.

Roy Lewallen, W7EL

When I lived in Florida, the largest wire antenna that I could get in my attic was a bent 40m dipole (that worked quite well at 40m). When tuning to 75-80m, I could hear all the stations with very little noise background. When I came up hear and was able to experiment with wire antennas, I learned that on the 75-80m band, using an antenna tuner, that as you began to become a resonant circuit on 75-80 you heard a lot of noise. At that point, as your VSWR through the tuner-antenna approached 1-2 where you could actually transmit, the noise on the transdceiver was/is (as we all know) very high on these bands.

When other people complianed of noise, it was a common practice for them to use 2 transceivers or a transmitter with a separate receiver on 75 80m. The transmitter of course was tuned as close to 1:1 as possible but the receiver was tuned to a higher VSWR to 'tune-out' the noise, yet the signals higher than noise came through very well. I was actually quite surprized to find out how much noise there was on 75-80m when I was actually able to transmit/receiver at a VSWR close to 1:1.

This was/is something other people do routinely and is somewhat better than an old wivws tale. Of course, by not tuning in the noise, you risk not tuning in the very weak stations but you can come to an accomodation where you hear mostly what you want to hear while getting rid of noise. The attenuate button does not work as well for this (my opinion).

> If so, what do you suppose the mechanism is by which the shorter antenna
> distinguishes between signal and noise?

If the antenna has a high VSWR, although you cannot transmit efficiently, signals significantly stronger than noise level can still be received, or so I think as do others. I am not sure at this time 'why' the gain of the noise

is not comparable to that of stronger signals when adjusting the receicver for normal listening volumes. But when listing at 80m, you can simply take a 20 foot piece of wire and hang it indoors and you will hear a lot of stations quite clearly and the noise level will be much lower than when you tune it resonant.

For me, Yeasu 747 and icom IC718 (as you can see on my QRZ photo). These are fairly decent receivers. There were no front end overload effects; the signals were located skip distances for 75-80m with nothing local nearby (except maybe "noise", and it just occurs to me that local "noise" from powerlines or whatever could be overloading my front end...hmmm...not sure).

On Dec 9, 9:36 pm, Roger <rspa...@elltel.net> wrote:

The constantly-in-phase traveling wave concept requires the
difficult-to-believe observation that a directional ammeter placed very
near the end of an open transmission line will read the same current as
if it were placed at the source end. Perhaps someone can perform that
experiment some day, but I can not imagine how it can be done without
placing a load on the line, thus invalidating the initial assumptions.

The experiment will show the expected result but will
not help understand why. For that, examination of
the measurements and arithmetic performed by
a directional ammeter is useful.

Below, all voltages and currents are instantaneous.

Total voltage, Vt = Vf + Vr
Total current, It = If - Ir

Vf = If * Z0
Vr = Ir * Z0

Substituting....

Vt = (If + Ir) * Z0
Ir = Vt/Z0 - If

If = It + Ir
If = It + (Vt/Z0 - If)
If = (It + Vt/Z0)/2

Similarly, Ir = (It - Vt/Z0)/2

The directional ammeter measures instantaneous
Vt and It, does the above arithmetic and presents
If. A directional ammeter that presents a single
number rather than the time varying If has probably
converted the instantaneous values to RMS.

Examing It and Vt at various points on the line
and doing the above arithmetic will reveal why
the same value for If is obtained everywhere.

Directional wattmeters are more common
than directional ammeters. A directional

wattmeter does the above arithmetic then
squares If, multiplies by Z0 and presents
the results in watts.

All this from just measuring Vt and It.

...Keith

Hi Keith,

Thanks to you and others for responding on this side issue. It was
very helpful to me and resulted in a vast improvement in how I
understood the theory behind directional watt meters. I had the
misconception that current pickup over some lineal distance of
transmission line was NECESSARY for the device to work, but now clearly
understand that instantaneous measurement points suffice (and that
instantaneous current measurement may be impossible).

After considerable thought, I think the math you presented above is for
one of two cases of reflective waves, the reflection from a higher
impedance load. When the load is less than the Zo of the line, the
currents add but voltages subtract. Right? The end result is the
same for both cases.

To elaborate, the power (Pt) resident on the transmission line will
always be the sum of forward power and reflected power. Mathematically:

Ptotal = Pf + |Pr|

Pt = If * Vf + |(-Ir * Vr)| (Case of load impedance greater than
line impedance) (Case 1)

or

Pt = If * Vf + |(Ir * - Vr)| (Case of load impedance less than
line impedance) (Case 2)

Notice that Pt is always the ABSOLUTE SUM of the two power terms
because the reflective power always carries a negative sign on either
the current or voltage term. As a result, the summed value of the
resident power on a mismatched line is always greater than the actual
power going to the load.

Your example was correct for Case 1. I will show only Case 2.

Vt = Vf - Vr

It = If + I r

Vf = If * Z0

Vr = Ir * Z0

Substituting...

Vt = (If - Ir) * Z0

Ir = If - Vt / Z0

If = It - Ir

If = It - If + Vt/Z0

If = (It + Vt/Z0)/2

Similarly, Ir = (It - Vt/Z0)/2

The results are the same for both Case 1 and Case 2.

Agreed?

> while the system is 90 "electrical degrees".

Yes, you have just discovered that a 100 to 600 ohm
impedance discontinuity *loses degrees* when the 600
ohm end is open. That's why a center-loaded mobile
antenna takes more coil than a base-loaded mobile
antenna. Think about it.

Hint: if the stub is open, the low Z0 needs to be
placed at the open end to make the stub physically
shorter.

If the stub is shorted, the high Z0 needs to be
placed at the shorted end to make the stub
physically shorter.

You seem to be surprised at that. One wonders why?

I note you are distancing yourself somewhat from this explanation, but
apparently supporting it. A foot in both camps.

Is the assertion supported by any sound technical explanation.

Roy gave one possible explanation of why reducing receiver input may
improve S/N ratio, but you later dismiss that (RX IMD noise) as a likely
explanation.

Fundamentally, wouldn't you expect S/N to degrade in a linear receiver
system as you decrease the Signal+Off-Air-Noise wrt the receiver
equivalent internal noise?

Have you actually measured and documented the claimed improvement, or can
you cite a reliable experiment? Can you really dismiss RX IMD noise as a
significant contribution? Do you have another likely explanation?

> This was/is something other people do routinely and is somewhat better
> than an old wivws tale. Of course, by not tuning in the noise, you

So, if it cannot be measured, if it cannot be explained, isn't it no more than an old wives tale?

Owen

That statement is slightly misleading. The length of the transmission line can be converted to time, e.g. one microsecond long. If the forward power is 100 joules/sec and the reflected power is 50 joules/sec, the total energy in the one microsecond long transmission line will be 100+50 = 150 microjoules. Energy is what is flowing in the feedline and must be conserved, not power.

The technically correct way to say what you are trying to say is: There is exactly the amount of energy resident in the transmission line needed to support the steady-state forward and reflected power readings. I realize that I am picking nits.

> How does one compute the phase shift at the terminals?

I use the smith chart in my response.

If you have 3 black boxes each labeled "input impedance = -j567", they could contain a number of different things but since I am using the smith chart, they will contain 3 different lengths of open transmission lines.

Box 1 contains 10 degrees length at 4MHz of 100 ohm transmission line. Based on VF=1, this line would be 3/4*E10E2*10/360 = 2.08m long.

On the smith chart, plot from circle 10 degrees (transmission coefficient) and read -j5.67. Normalize to 1 = 100. The impedance at the input of the line is -j567. Label this box "input impedance = -j567".

Box 2 contains 19.2 degrees length at 4MHz of 200 ohm transmission line. Based on VF=1, this line would be 3/4*10E2*19.2/360 = 4.0m long

On the smith chart, plot from infinte impedance circle 19.2 degrees (transmission coefficient) and read -j2.84. Normalize to 1 = 200. The impedance at the input of the line is -j(200*2.84) = -j567. Label this box "input impedance = -j567".

Box 3 contains 27.2 degrees at 4MHz of 300 ohm transmission line. Based on VF=1, this line would be 3/4*10E2*27.2/360 = 5.67m long.

On the smith chart, plot from infinte impedance circle 27.2 degrees (transmission coefficient) and read -j1.89. Normalize to 1 = 300. The impedance at the input of the line is -j(300*1.89) = -j567. Label this box "input impedance = -j567".

So, do all boxres labeled "input impedance =-j567 ohm" transmission lines behave the same when connected to the 600 ohm transmission line?

No.

For each of these, impedance at the discontinuity will be -j567. However, each has different electrical lengths, thus the 600 ohm line connecting to it will have to be cut to different electrical lengths, for all of the degrees to add to 90 total.

You can only say that all -j567 of a given Zo will affect phase shifts in connected 600 ohms lines in the same way.

So far, I find this very interesting. Not all -j567 impedors are equal when it comes to transmission lines.

Certainly the noise level will be lower than when you match the antenna.
but so will the signals. In exactly the same ratio. And if you can hear
the signals clearly with the short antenna, you can hear them just as
clearly with the longer one -- unless you're overdriving something to
the point of nonlinearity with the longer antenna.

If you think you're actually improving the signal/noise ratio by
mismatching the antenna, then you've claiming that mismatching has
somehow given it the ability to tell the difference between what you
regard as "signal" and what you regard as "noise" even though both are
presumably on the same frequency. Or perhaps if the signal and noise are
coming from a different direction, the mismatch is causing a change in
the antenna's directional pattern. Neither of these fits with any known
theory, so I'd have to see some really solid quantitative measurements
to be convinced this is more than an old wives' tale. (And even then,
I'd be looking very hard for an explanation that fits the theory which

has suited us so well for over a century.)

Mismatching the antenna should do no more nor less than turning down the RF gain control. Have you tried doing that instead?

Don't worry about the noise.

Construct the best possible setup you can. Pay close attention to matching the impedance to the receiver. Use quality/high-freq semiconductors, even better than required/stated--if possible, keep those noise figures low. Remove the antenna away from any potential noise source as you possibly can. Keep the antenna as high as you possibly can. Place the antenna where it will get the largest possible view of the heavens/horizon. Use as Hi-Q coil/cap as you can, to narrow the bandwidth as much as can be logically tolerated. Keep the coax/feeder as short as is logically possible and the run away from noise sources. Etc. ...

Now, worry about what you can do to help with noise reduction ... if you find you have too much gain, drop a gain control in ... filters?

Regards,
JS

I wouldn't expect it to change by any discernible amount at HF, until the antenna gets very short or very mismatched. The noise figure of most HF receivers is good enough, and the atmospheric noise high enough, that it takes a poor antenna indeed before the receiver noise becomes apparent. This is certainly emphatically true on 80 and 160 meters in Florida.

No I did not!

First I said "There were no front end overload effects; the
signals were located skip distances for 75-80m with nothing local nearby

But then I said:

"(except maybe "noise", and it just occurs to me that local "noise" from powerlines or whatever could be overloading my front end...hmmm...not sure)."

Which is another way of saying "Hey, maybe you're right. Maybe strong signals from locally generated noise IS overloading my front end."

I don't dismiss things that Roy says as a casual thing. Even he wasn't saying this was absolutely the case. But I think he might be right. I learned something from his suggestion.

Of course not. Geeze, when somebody says "hey, during net operations in the summer I use a separate tuner with a length of wire as a receiving antenna to lower the noise level", we do not proceed to define a scientific project to prove the claim is true. Unless you might be interested in providing funding for such a study in which case I could begin my early retirement.

Agreed Roy.

My graphic at http://www.vk1od.net/bpl/AreYouReady.htm shows the IRU-R P.372-8 predicted galactic noise levels to be some 35dB above a good receiver noise floor at 80m, and man made noise and especially atmospherics are well above that.

Harking back to IMD noise, it is a result of non-linearity in the receiver (front end usually), and can be improved by reducing the level of unwanted (ie out of band) signals reaching the electronics. Any form of front end filtering (like a detuned ATU) that favours out of band signals relative to inband will only exacerbate IMD noise, not improve it, so the proposed technique should not improve IMD noise.

As you noted, IMD noise can be an issue with a substandard receiver... for example I experience it with an Icom IC-R20 on a half wave dipole on 80m. I agree with you that most good receivers should have very low noise from IMD, so that AI4QJ's proposition without an apparent explanation.

Owen

I think you were right, it is a front end overload issue. But I think adding an attenuator that simply reduces all input signal strength in a linear manner does not act the same as de-tuning. Comments from others on their experiences would be interesting. It is easy enough to try out out; just find a strong 75m station and using a tuner, tune out the noise and see if you can still receive (and more pleasureably). Is this the same as attenuating all input signals 20dB? I lack a technical explanation and we haven't agreed that the effect is real so I will drop out of this discussion unless someone else wants to pick it up.

The full paragraph was:
For me, Yeasu 747 and icom IC718 (as you can see on my QRZ photo). These
are fairly decent receivers. There were no front end overload effects;
the signals were located skip distances for 75-80m with nothing local
nearby (except maybe "noise", and it just occurs to me that local
"noise" from powerlines or whatever could be overloading my front
end...hmmm...not sure)"

I have interpreted "For me, Yeasu 747 and icom IC718 (as you can see on
my QRZ photo). These are fairly decent receivers. There were no front end
overload effects;" to be fairly definite.

"There were no front end overload effects;", it is about as clear as "I
did not have sex with that women"... but we all know what theat mean't.

I am not trying to misrepresent you, it is about the value you put in
your own written words.

Owen

I assume you are missing the word "is" in the second clause but I need to further correct your statement by changing the word "proposition" to "observation". Go ahead and impeach my and others' "observations". Better to dismiss observations that may be difficult to explain as not having been actually observed. We should keep our observations to ourselves.

```

I already explained I tend to agree with what Roy said when I consider the effects of locally generated high levels of noise. I am not going to get into a semantic discussion.

How violently must I agree with Roy before you believe me?

The signal itself is coming from an avalanche transceiver (a pulse at 457khz every second or so) which has a relatively small antenna and the signal attenuates quickly , most receivers only have about a 25m straight line range and I'm trying to improve on that. I thought the small range was due to the weakness of the signal, I'm a bit clueless as to how much of the problem would be from radiant noise, although these posts are starting to give me some insight. Thanks for the help thus far.

I agree that "almost periodically" is a bad choice of words. It is professor
talk, taking a certain amount of literary license.

The standing wave equation looks like cosine(kx)*cosine(xwt). The outer cosine function essentially describes the envelope of the standing wave along the distance kx and not time. I think he is saying it "looks like the familiar cosine function that we see in periodic waves" where period is related to time 1/f but it really is not "period" in the true definition. "Distance" is not defined as a "period", that would have to be "time".

The inner cosine function describes the time function where at every point kx, there is a periodic cosine function where the value oscillates in time as a cosine periodic wave of maximum/minum vaklues determined in time by the cosine function of the distance kx at that point. However, anyone can see what he means and he would probably consider the issue trivial and change his wording if he thought it caused confusion.

3182. Front ends ...

I have gotten back into SWL'ing lately ... (ain't like it used to be either!)

Got a couple of old Hallicrafter receiver rigs and replaced the front end tubes with some GaAs semi circuits, done on a pcb board and serves as a direct replacement for the tubes--except for the need of filament current, they are "work-a-likes" ... gawd, bet those old boys wish they would've have had those when they engineered the rigs ... I just love the look of these old "solid" rigs! (solid as in "weighs a ton!)

I am interested in anyone else who has "tweaked" old rigs with various "kludges" and gotten good results? Comments? Advise? Construction? Results? Ideas? Unique construction? Anything? ...

Now, this post might NOT be "right on topic" for antennas, but darn close, we DO have to consider what our antennas feed, right?

Warm regards,
JS

Let's take a look at what mismatching does.

At the frequency you're listening to (and for practical purposes some bandwidth on either side), mismatching does the same as an attenuator -- it simply reduces the strength of the incoming signals and noise by the same factor. (It has to reduce both by the same factor because neither the antenna nor the tuner has any way of distinguishing which is which.)

At other frequencies the story is a bit different. Assuming you don't want to listen to other frequencies at the same time, everything off-frequency can be categorized as noise. Adjusting your tuner will cause the match to improve at some frequencies, increasing the noise at those frequencies which reaches your receiver. It will also degrade the match at other frequencies, decreasing the noise from those frequencies which reaches your receiver. A good quality receiver will reject the noise at all frequencies except the bandwidth you're intentionally listening to, so increasing or decreasing the noise at those frequencies shouldn't make any difference, and again the result won't be any different from an attenuator. Only if off-frequency noise is strong enough to cause your receiver to distort will the mismatching have any effect that might be different from an attenuator. If that's the case, different mis-tunings will have different effects depending the frequencies of the overloading signals and which frequencies are favored or not favored by the mis-tuning -- mis-tuning could make matters better or worse.

There's an added wild card here if the receiver is being overloaded and creating intermod. Two off-frequency signals ("signals" in the broad sense, here, which includes both noise and intentionally transmitted signals) can combine to produce an in-band intermod product which you'll hear and regard as noise (this also in the broad sense, meaning anything you don't want to hear). This intermod product isn't on frequency until after the receiver front end, because that's where it's created. Messing

with the tuning could possibly attenuate one or both the offending signals more than an attenuator would, so you'd see more of an improvement in S/N ratio than with an attenuator. I think this would only be an occasional lucky happenstance, though, and not something you'd consistently see. But a plain attenuator can provide quite a dramatic improvement when intermod is present. Adding 10 dB of attenuation ahead of the receiver will reduce your desired signals and in-band noise by 10 dB. But it'll reduce second order intermod products by 20 dB, third-order products by 30 dB, etc. So an attenuator (or mis-tuning or a smaller antenna) can provide a real S/N ratio improvement when some of the noise is intermod being created by your receiver. A preselector can also be helpful in this situation. Again, though, you won't see this with a quality receiver unless you have some remarkably huge off-frequency signals. I wouldn't be too surprised to see it on 40 meters in Europe, for example.

As Tom says, once your antenna is good enough to make atmospheric noise louder than receiver noise, you can't do anything to further improve the S/N ratio unless you can null out some noise from a single direction (or opposite directions). And it doesn't take much of an antenna or receiver to do that at this frequency.

The only way to improve range, then, is to make the transmitted signal stronger with respect to the atmospheric noise. To do that, you'll need to increase the strength of the transmitted signal by increasing transmit power or improving the efficiency of the transmitter antenna.

Wait a second.

You have three black boxes, all of which present an impedance of -j567 ohms at some frequency.

And you say that you can tell the difference between these boxes by connecting a 600 ohm line to each one? If so, please detail exactly what you would measure, and where, which would be different for the three boxes. I maintain that there is no test you can devise at steady state at one frequency (where they're all -j567 ohms) which would enable you to tell them apart. I'll add a fourth box containing only a capacitor and include that in the challenge.

If you agree with me that you can't tell them apart but that connecting a 600 ohm line gives different numbers of "electrical degrees", then I'd like to hear your definition of "electrical degrees" because it would have to be something that's different for the different boxes yet you can't tell the difference by any measurement or observation.

Oh yeah, somethin' Roy said, making the antenna "directional."

Lucky you, that ~1ft. long ferrite rod is a dream for it, use aluminum foil shielding!

Just place some foil on the side(s) of the rod you have no interest in getting a signal from.

If you doubt the effectiveness of this, wrap a 1ft. "circle" of foil around the darn ferrite antenna (DON'T short the ends of the foil--so as to complete a "shorted turn." And, you'll get a lot of silence with this shield ... you might even find it works rather well. :-)

These guys, most likely, consider you a "slow cousin." Heck, I'll give 'ya the benefit of the doubt--you'll figure it all out--and, probably, and most likely, quickly!

I like your questions, makes me remember when I played around with similar stuff ... good luck!

3189. Calculating a (fictitious) phase shift; was : Loading Colis

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-12 09:16:03 UTC
From: David Ryeburn <ryeburn@sfu.caz>
Message-ID: <ryeburn-343CEB.01160212122007@morgoth.sfu.ca>
Source record: 31546

Several people (perhaps best not named) have said various things about a "phase shift" occurring at the junction of two (lossless) transmission lines of different characteristic impedances, if one of them is terminated in an open circuit. In particular there has been discussion of a 100 ohm line with an open circuit for its load, attached to a 600 ohm line, and with the "electrical lengths" of the two lines chosen in ways making the other end of the 600 ohm line appear to be a short circuit.

In one case, the 100 ohm line was 10 degrees long, the 600 ohm line was 43.4 degrees long, and the discontinuity at the junction between the two lines was blamed for the missing 36.6 degrees. In another case, the 100 ohm line was 5 degrees long, the 600 ohm line was 62.3 degrees long, and the discontinuity at the junction between the two lines was blamed for the missing 22.7 degrees.

I prefer to think of it this way. The open-ended 100 ohm line section of length alpha degrees presents an impedance of -j*100*cot(alpha) to the 600 ohm line. (Call this 600 ohm line, which gets terminated by the 100 ohm line, the first 600 ohm line section.) This impedance presented to the (first) 600 ohm line section by the 100 ohm line section is the same impedance that would be presented to the (first) 600 ohm line section if instead it were to be terminated with another (second) length of 600 ohm line, not of length alpha but rather of length (alpha + beta), so we have

-j*600*cot(alpha + beta) = -j*100*cot(alpha)

This equation can be solved for beta, which is going to represent the (fictitious) phase shift. Now if we want the other end of the (first) 600 ohm line to look like a short circuit, then we will want the (first) 600 ohm line to have length 90 - (alpha + beta) degrees.

All this really has nothing to do with the special values 100 and 600 ohms. If the open-circuited line has characteristic impedance Z_1 and the other line has characteristic impedance Z_2, then the Z_1 impedance line presents a load of -j*(Z_1)*cot(alpha) to the Z_2 impedance line section, the same load that would have been presented to the Z_2 ohm line section had it instead been terminated by another piece of Z_2 ohm line of length (alpha + beta), or in other words

-j*(Z_2)*cot(alpha + beta) = -j*(Z_1)*cot(alpha).

Dredging up from memory the formula for the tangent of the sum of two angles (a formula which I probably last used in high school nearly 60 years ago) and solving for beta,

beta = arctan{[(Z_2) - (Z_1)]*tan(alpha)/[(Z_1) + (Z_2)*(tan(alpha))^2]}

This formula agrees with the values previously given for the 10, or 5, degree 100 ohm line, and 600 ohm line combinations. If Z_1 = 100, Z_2 = 600, and alpha = 10 degrees, the formula gives beta = 36.6132921 degrees. Using the 5 degree length instead for the 100 ohm line, beta = 22.6964176 degrees.

Note that beta depends only on Z_1, Z_2, and alpha (the length of the open-circuited Z_1 ohm line), and not on the length (call it gamma) of the Z_2 ohm line. If you want some other impedance, say W, instead of zero ohms, to be presented at the input to the Z_2 ohm line then just make sure the Z_2 ohm line has length gamma, where

-j*(Z_2)*cot(alpha + beta + gamma) = W.

Of course, for lossless lines, W had better be a pure imaginary number. (The choices W = 0 and W = infinity are OK.)

I really don't think beta is of any importance, nor that it has any physical meaning. What is important, and does have meaning, is (alpha + beta). That's the length that a (second) section of open-circuited Z_2 ohm line would have to be, to have the same effect on the (first) section of Z_2 ohm line that the open-circuited Z_1 ohm line section has. Once you mentally replace the Z_1 ohm line section with such a Z_2 ohm line section, everything becomes much simpler.

If you want more than just two line sections of different impedances, this approach is easily adapted to that situation. Just take things one stage at a time.

I think these formulas don't care whether the angle alpha is acute, whether Z_2 is larger or smaller than Z_1 (or even the same), or whether the desired input impedance W is that of a pure capacitance (negative imaginary W) or of a pure inductance (positive imaginary W) or represents a short circuit or an open circuit. If you don't like negative coax cable lengths, negative angle values for gamma can be avoided by adding 180 degrees. Negative values for beta are no problem, as long as (alpha + beta) is positive -- they just mean that the Z_2 ohm cable thinks the open-circuited Z_1 ohm cable is shorter than it really is, instead of longer. Notice that that is exactly what happens when Z_1 is larger than Z_2 (assuming alpha is acute).

Thank you for this tentative...
So lets keep on 2m for the simplicity.
I know that you do not put a vertical dipole on a roof.
You put it on a mast, and this mast (if small) can be on (side of) car
when on halt...
The link budget will change by the fact that the dipole will be
higher. (easy to take in account in a formula like Eggli-Mod for
example). But there should be also a difference in Antenna Gain.
That's what I'm looking for!

Pierre

Ooooppppss. My apologies to Johnson.

I suppose I have just proved my own point that
taking sentences out of context can lead to
incorrect interpretations.

The debate has never been aoout a little looseness
in the terminology; i.e. does "power flow" or does
"energy flow". That is a straw man of your own
making.

The debate is over much more fundamental issues.

When mounting an 2 m antenna on a car you do not care for gain.
Care for good SWR on 2 m and 70 cm which is difficult enough
to obtain with a combined radial.
The direction characteristic of the antenna + car assembly is
totally unpredictable. Just try to have good horizontal radiation,
else you will only heat up the atmosphere.

The best place is in the center of the roof for a metal case car.
If you bought a plastic car, well, then you bought plastic.

An impedor has an impedance but all impedances are not
impedors. The IEEE Dictionary gives three different
definitions for "impedance".

> Keith Dysart wrote:On Dec 9, 9:36 pm, Roger<rspa...@elltel.net>wrote:The constantly-in-phase traveling wave concept requires the difficult-to-believe observation that a directional ammeter placed very near the end of an open transmission line will read the same current as if it were placed at the source end. Perhaps someone can perform that experiment some day, but I can not imagine how it can be done without placing a load on the line, thus invalidating the initial assumptions.The experiment will show the expected result but will not help understand why. For that, examination of the measurements and arithmetic performed by a directional ammeter is useful. Below, all voltages and currents are instantaneous. Total voltage, Vt = Vf + Vr Total current, It = If - Ir Vf = If * Z0 Vr = Ir * Z0 Substituting.... Vt = (If + Ir) * Z0 Ir = Vt/Z0 - If If = It + Ir If = It + (Vt/Z0 - If) If = (It + Vt/Z0)/2 Similarly, Ir = (It - Vt/Z0)/2 The directional ammeter measures instantaneous Vt and It, does the above arithmetic and presents If. A directional ammeter that presents a single number rather than the time varying If has probably converted the instantaneous values to RMS. Examing It and Vt at various points on the line and doing the above arithmetic will reveal why the same value for If is obtained everywhere. Directional wattmeters are more common than directional ammeters. A directional wattmeter does the above arithmetic then squares If, multiplies by Z0 and presents the results in watts. All this from just measuring Vt and It. ...KeithHi Keith,
> Thanks to you and others for responding on this side issue. It was very helpful to me and resulted in a vast improvement in how I understood the theory behind directional watt meters. I had the misconception that current pickup over some lineal distance of transmission line was NECESSARY for the device to work, but now clearly understand that instantaneous measurement points suffice (and that instantaneous current measurement may be impossible).
> After considerable thought, I think the math you presented above is for one of two cases of reflective waves, the reflection from a higher impedance load. When the load is less than the Zo of the line, the currents add but voltages subtract. Right?

I don't think so.
Vt = Vf + Vr, It = If - Ir, Vf = If * Z0 and Vr = Ir * Z0 are the
fundamental
equations defining forward and reverse waves.

Perhaps you arrive at two choices because sometimes Vr and Ir
are negative, which after simplification appears to give an
alternate form?

> The end result is the same for both cases.

This is good. If you chase the signs, though, I think you will find
that there is only one case.

We probably should not toss Power into the mix until agreement
is reached on this. Power is fraught with issues which seriously
confuse some.

To find the length of the 600 ohm line, do I not just plot -j567/600
and work from there? It seems to me that it yields the same
answer regardless of the content of the black box.

Actually, I believe that every disagreement between Jim Kelley and myself has been semantic in nature. There are no technical fundamentals upon which we disagree.

We both agree that a light wave from Alpha Centauri that hits the earth has transferred energy.

We disagree about a light wave from Alpha Centauri that misses the earth. I say the energy in the light wave is in the process of being transferred. Jim disagrees.

> The debate is over much more fundamental issues.

Like what? The definition of "transfer"?

I think Roger is talking about the phase shift at a reflection
point. If ZL > Z0, the current reverses phase, i.e.
It = |If| - |Ir| = 0. If ZL < Z0, the voltage reverses phase,
i.e. Vt = |Vf| - |Vf| = 0

The sign on the reflected current is just a directional
convention left over from DC and is unnecessary as the phase
angle of the phasor values takes care of the signs.
Interestingly, the field of optics has a different convention.

Left out a few words - should be:

It = |If| - |Ir| = 0 at an open-circuit.

Vt = |Vf| - |Vr| = 0 at a short-circuit.

There are certainly many experiments one can conduct
to deduce an equivalent circuit for the interior of the black
box.

But for this sub-thread, which started with 90 "electical degrees",
a single frequency seems to me to be strongly implied.

So this means I could take an antenna element
which is longer than 90 physical degrees, i.e.
greater than 1/4WL, and with the appropriate
matching network make a system that was
90 "electrical degrees".

I detect progress on the definition.

Hi OM,

Rubber Ducky performance is an unknown quantity, but certainly can be
improved.

>Gain difference between vertical ground plane and dipole is about 2dB.
>
>What I'm looking for is the gain difference between
>
>portable whip
bad, maybe
>1/4-wave on car roof
OK, maybe
>5/8 on car roof
better, maybe
>Vertical dipole
OK, maybe

All such valuations vary a lot with height. With enough height, you
could use a rubber ducky anywhere.

>Does anybody have more info?

It would be simpler if you examine exactly your situation using EZNEC.
The free version should be capable of doing a lot of this.

> 90 "electrical degrees".

Of course, if you reverse the position of the
600 ohm line and 100 ohm line in the previous
open-stub example, you will *lose* 8.3 degrees
of phase shift at the impedance discontinuity.
The transmission line will have to be physically
98.3 degrees long to get an electrical 90 degree
phase shift.

In like manner, if you have a straight (Hustler)
base rod and make the rest of the antenna a
helical coil with no stinger, you will wind up
with a resonant mobile antenna that is more than
90 degrees long physically.

If the Z0 of the base rod is 400 ohms, the
Z0 of the loading coil is 4000 ohms, and the
length of the base rod is 10 degrees, you will
lose 9 degrees at the base rod-to-coil impedance
discontinuity. The coil will need to be 89 degrees
long, i.e. almost self-resonant. The antenna will
be 99 degrees long physically.

Great thought on making it directional, hopefully even the slow cousin
can figure out how to wrap foil.

As for the receiver would a simple MK484 based one suffice? Or would a
Superheterodyne provide better performance?

Lastly is their a cheap commercially available receiver I could plug
my antenna into to compare the performance to my home built one?

Thanks,
Chris

The ducky that came with my DJ-580 was an abomination.
I replaced it with a long Diamond ducky and a Tiger
Tail and gained about 6 dB if memory serves me right.

Hi John,
You might want to post in the boatanchors group or the shortwave group
also.
I well recall collecting "tubistors" at Dayton some years back for a friend
who wanted them for his S line. They were plug in replacements for the
tubes.

Wes Hayward had a picture of a KWM-2 partly protruding from a bin labeled "Old Junk". I believe he included it in his _Solid State Design for the Radio Amateur_. The explanation is that it had been modified by replacing well designed, high dynamic range tube circuits with much poorer solid state circuits by someone who didn't understand the principles of high dynamic range circuit and receiver design. The result was a receiver with very poor intercept values and consequent severe problems with intermod and other spurious responses. The well-meaning modifier had turned a very good receiver into Old Junk.

Keith Dysart wrote:
> I detect progress on the definition.

Are you ready to find out why center-loading takes
more coil in a mobile antenna than does base loading?

Take the 10 degrees of 100 ohm line and move 5
degrees of it to the other end of the stub.

From this:

---43.4 deg 600 ohm line---+---10 deg 100 ohm line---open

To this:

--5 deg 100 ohm line--+--600 ohm line--+--5 deg 100 ohm line--open

Now how many physical degrees of 600 ohm line is needed
to make the stub electrically 1/4 wavelength?

I'm not surprised to hear this Roy. I also believe the tubistors were a short lived product- sought after by BA collectors.

True, I have never seen a fet(s)/MMIC do anything a tube, or a few
tubes, can't do--the solid state devices just do it better ...

Your text brings the old nuvistors back to mind ... hot devices, for
their time. As I remember, whether correctly or not, they were offered
by the tube manufacturers in an attempt to compete with transistors--a
failed attempt ...

The MK484 should be a good device for your project, almost everything
you need on a single chip. I have used the ZN414, these devices were
fun to play with ...

Ham swaps are a good place to look for "cheap" equipment ...

You should be able to set up the MK484 as "hot" as you would like ...
why bother with looking for other equip? Chuck a low noise MMIC in
front and off 'ya go ... as others point out, noise will be your only
limiting factor.

Would be interested in how your final project turns out ... keep me
posted if possible ...

ITYM Nuvistors ?

I have both a 6M and 2M converter made by AMECO that are populated with Nuvistors. I use them with an NC-303 (have 2 of'em) during periods of manic nostalgia.

No _there's_ a boat anchor: The NC-303! When I was a much younger man I could actually lift it up onto the workbench all by myself...

I remember them from the 1970's as "Fetrons" Similar devices I think.

I also know from experience it wasn't a good idea to replace the valve
HT rectifier with silicon diodes, without a dropper resistor.

Some years ago, I worked on a project to replace tubes in a receiver with fetrons. The problem was that the fetron had to be designed for a particular spot in the radio. For example, we couldn't find a design for a 5763 replacement that would work in any socket in the radio that used a 5763. We had to design a fetron for every circuit use--rf amp with agc, rf amp without agc, etc. even though the tubes could be taken from stock and plugged in any hole. In the end, some of the circuits remained with tubes.

You will have a lot of fun doing that conversion, but it will be a lot of work to get optimum performance.

In this case, electrical degrees = physical degrees. VF = 1.

I'm a little at a loss as how to "chuck" a low noise mmic in front. I thought these were reserved for higher frequencies. I had trouble finding much info as to how I could use one. I did find this little guy as an alternative:

Amtel ATR5261
http://www.atmel.com/dyn/resources/prod_documents/doc4913.pdf

Could I use that as a low noise amp?

And to clarify, I could have some connection such as: antenna ----> lownoiseamp ------> MK484 ------> amplifier (LM386?) ------> speaker

Thanks for bearing with my limited knowledge. I think it could be useful little deal if it ever turns out.

-Chris

I see your point. To end up with -j567 on a 200 ohm line, you must use
19.2 degrees of length. 19.2 degrees of 200 ohm line brings you to -
j2.84 on the smith chart. To get -j567 on a 100 ohm line, you only
need to go 10 degrees, corresponding to -j5.67 on the smith chart.
Although we know that the 200 ohm line is longer, there is no
indication that the length of the 600 ohm line must or must not
change. I cannot know that unless I know the change in phase angle at
the new -j567 discontinuity with the 200 ohm line. I do not have
enough information on that unless I measure it, as was assumed to be
the case using the 100 ohm line. I was assuming that the phase change

at the discontinuity would not change but it is not immediately obvious that it will or will not. Then, if it did not change and stayed at 37 degrees, you would have had a new length of 600 ohm line of 90-37-19.2= 33 degrees which at VF =1, l = 33/360*75 = 6.875m. I do not have the information available to make that assumption. I would have to resort to measurement, same as was done with the 600-100 ohm combination.

I see your point. I assumed that the phase change specific to the discontinuity was the same for all -j567 impedances. I do not have the information to say it is true (or I lack the tools to prove it).

To end up with -j567 on a 200 ohm line, you must use 19.2 degrees of length. 19.2 degrees of 200 ohm line brings you to -j2.84 on the smith chart. Then, 200* -j2.84 = -j567. To get -j567 on a 100 ohm line, you only need to go 10 degrees, corresponding to -j5.67 on the smith chart. The 100* -j5.67 = -j567. Although we know that the 200 ohm line is longer by 9.2 degrees, there is no indication that the length of the 600 ohm line must or must not change. I cannot know that unless I know the change in phase angle at the new -j567 discontinuity with the 200 ohm line. I do not have enough information on that without additional measurements. I would need to measure it to to system resonance (1/4WL = 90 degrees), as was the case using the 100 ohm line. I was assuming that the phase change at the discontinuity would not change but it is not immediately obvious that it will or will not. But, assuming (rightly or wrongly) that the phase angle at the discontinuity did not change and stayed at 37 degrees, you would have had a new length of 600 ohm line of 90-37-19.2= 33 degrees which at VF =1, l = 33/360*75 = 6.875m. I cannot make that assumption right now. I would have to resort to measurement, same as was done with the 600-100 ohm combination.

In any case, this does not disprove the basic premise of the existence of a phase change due to the impedance discontinuity. It does prove that my minor point of elaboration may have had a false assumption.Sorry for any confusion.

The phase shift at the impedance discontinuity depends
upon the *ratio of Z0High/Z0Low*. The following two
examples have the same phase shift at the impedance
discontinuity.

Z0High Z0Low

---43.4 deg 600 ohm line---+---10 deg 100 ohm line---open

---43.4 deg 300 ohm line---+---10 deg 50 ohm line---open

So how long does the 600 ohm line have to be in the following
example for the stub to exhibit 1/4WL of electrical length?

---??? deg 600 ohm line---+---10 deg 50 ohm line---open

I don't care about your use of words, Cecil. I am only concerned with some of the concepts that you describe.

Those white floating things are way, way off in the distance and
nowhere near to approaching us. The chairs for the band remain in
place, folded up. The angle of the deck is 0 degrees horizontal.

Last time I used 'em, used a dc-to-1Ghz MMIC. But, a quick search of
net made your point hit home here, some begin bandwidth at 400+Mhz!
Maybe ebay, old stock?

>> I had trouble
> finding much info as to how I could use one.

This device: (click on the data sheet link on the page.)

http://www.datasheetcatalog.com/datasheets_pdf/U/P/C/1/UPC1651G.shtml

covers HF through UHF and is an example of the type of device I referred
to--in fact, this one may be usable for your needs (it is usually the
upper most freq that is limiting)--but, you should be able to find such
a unit, as this, which covers dc-1Ghz+ in its' specs.

This is a simple 4 terminal device: B+, Gnd, input, output ... your ant
to input, output to your front end ... simple!

>> I did find this little
> guy as an alternative:
>
> Amtel ATR5261
> http://www.atmel.com/dyn/resources/prod_documents/doc4913.pdf
>

Appears like an interesting device, however, also looks "overly complex"
for your particular needs ...

> Could I use that as a low noise amp?
>

Absolutely!

> And to clarify, I could have some connection such as: antenna ----
>> lownoiseamp ------> MK484 ------> amplifier (LM386?) ------>
> speaker
>

Looks good! And, why not just "breadboard" it first, then commit to
hard wiring it; such as this breadboard:
http://www.goldmine-elec-products.com/prodinfo.asp?number=G8534

> Thanks for bearing with my limited knowledge. I think it could be
> useful little deal if it ever turns out.
>
> -Chris

The longest journey begins but with a single step--don't let anything
discourage you. A breadboard and some parts and you are almost there ...

Regards,
JS

Sorry, I'm having trouble following that. But:

-- IF there's a phase change at the impedance discontinuity (which I assume means the black box terminals), it's the same for all four (your three and my one) black boxes. Whatever conclusions you might have drawn about the relationship between the phase change and the contents of the boxes, other than the impedance at the terminals, are wrong, and you should investigate where you went astray in the process of reaching those conclusions.
-- If you think you can distinguish the boxes by measurement (at the one single frequency at which all their impedances are the same, in steady state), show exactly how you'd do it and what the results would be. I claim that you can't.
-- If the four boxes have different numbers of "electrical degrees" at

the same frequency, then "electrical degrees", as the term is used here, is something you can't measure. That seems to be the case. And if you can't measure "electrical degrees", how do you determine how many of them are "missing"?

Of course, "electrical degrees" does have meaning. But like a number of other terms, some newsgroup participants have made up alternate meanings and given them properties which are nonsensical.

Roy Lewallen wrote:
> -- IF there's a phase change at the impedance discontinuity (which I
> assume means the black box terminals), it's the same for all four (your
> three and my one) black boxes.

To see exactly how wrong that statement really is let's
take a look at two of the cases.

(1) with a -j567 ohm impedor (capacitor) connected inside
the black box to the existing 43.4 degrees of 600 ohm
line external to the black box.

(2) with 46.6 degrees of 600 ohm line connected to the
existing 43.4 degrees of 600 ohm line external to the
black box.

The reflection coefficient for (1) at the black box
terminals is 1.0 at -93 degrees, i.e. 100% reflection
at that point with an accompanying phase angle shift.

The reflection coefficient for (2) at the black box
terminals is 0 at 0 degrees, i.e. no reflections at
that point and no accompanying phase angle shift at
that point.

To assert that the phase change at the black box
terminals is the same in both of those cases is
ridiculous. In case (1) it is 93 degrees. In case (2)
it is zero degrees.

I use words to describe those concepts. You and I do not
agree on the definitions of those words. Reality is what
it is. It is the different definitions that we are using
that is the problem.

For instance, what if I am using a different definition
than you are for "concepts" in your posting above? What
if you were writing in a language that I didn't understand?
The outcome would be similar to what we have now.

When you repeat those concepts back to me, they bear no resemblance to the concepts that I am trying to describe. That is proof that our disagreements are semantic. (The only other possibility is that you are unethical and are deliberately bearing false witness against me.)

I use words to describe my concepts. You and I do not agree on the definitions of those words. Reality is what it is. It is the different definitions that we are using that is the problem. "Transfer" is obviously one of those words. I say all EM waves transfer energy. You say not all EM waves transfer energy. It is simply that we are using different definitions of the word "transfer". There are many other words for which we have different definitions.

You and I might as well be trying to communicate in two foreign languages that neither one of us understand.

I remember the days when we'd have to go clear to the park in San
Francisco to hear the guy standing on the box ranting about his pet
theories. And now we can do it with the click of a mouse in the comfort
of our homes. Ain't technology marvelous!

We're filling up our minds with garbage
Garbage, garbage, garbage, garbage, garbage
What will we do when there's nothing left to read
And there's nothing left to need
And there's nothing left to watch
And there's nothing left to touch
And there's nothing left to walk upon
And nothing left to ponder on
Nothing left to see
And nothing left to be but . . .
Garbage, garbage, garbage, garbage, garbage

So, when you are presented with 43.6 degrees of
600 ohm line connected to a black box (about
which you know nothing of the internals) which
provides an impedance -j567, do you answer the
question: What is the impedance at the input
of the 600 ohm line? Or do you refuse, because
you do not know what phase change is
occuring at the terminals?

...Keith

To you, they may not. But those concepts remain just as ludicrous no matter who describes them. :-)

> That is proof that our disagreements are
> semantic. (The only other possibility is that you
> are unethical and are deliberately bearing false
> witness against me.)

The obvious possibility being dismissed out of hand is the one where you are wrong and someone else is right.

> I use words to describe my concepts. You and I do not
> agree on the definitions of those words.

Yes. Others also use words, and there are cases where your understanding of the meaning of the words is not necessarily the same as the meaning intended by the author. We know this by comparing the things you say about physics with fundamental principles of physics.

> It is simply that we are
> using different definitions of the word "transfer".

If that is the case then I am using the definition pertinent to the physics of our discussion, and you are using whichever one you think will prevent your argument from containing a false statement.

> You and I might as well be trying to communicate in two
> foreign languages that neither one of us understand.

But only if it suits the purposes of internet one-upsmanship, apparently.

Can you expand on the two different interpretations of
"transfer" that will bring these views into alignment?

Perhaps you really are disagreeing on whether EM
waves always transfer energy (using the common
definition of "transfer").

Based on what you say above, Zo high/Zo low = 6 resul;ts in 37 degrees.
Then for phase shift, (Zo high/Zo low)*37 deg = 6*D where D = phase shift.

If the above ratio is literally true, then in the above example, 12*37deg/6
= 74 degrees and length of the 600 ohm line = 90-74-10 = 6 degrees.

However, I would like to find a reference for the math showing the
characteristic impedance ratio relationship with phase shift. I am reluctant
to accepting formulas without seeing them derived at least once. :-)

I'm not sure I understand the question. Measuring
the s22 parameter should be all we need to know.

No, that is not dismissed out of hand. I enjoy being wrong
because I always learn something new. You have not proved
me wrong because you haven't even understood what I said.

When you repeat what you think I said, and it is
not what I said, there is something wrong besides
someone being technically incorrect and someone being
technically correct.

Jim refuses to provide a reference for his definition of "transfer". My unabridged Webster's has 20 definitions for the word including, "to be moved from one place to another". I say the light waves from Alpha Centauri are transferring, i.e. moving energy from that star to other points in the universe. The Poynting vector for those light waves can be computed if necessary. EM waves cannot exist without energy.

Looks like you got the Z0 ratio upside down?

Actually I get 25.3 degrees for the 600 ohm line.

Arctan(Z0Low/Z0High)cot(10)) = 25.3 degrees

My vote is that they act the same. I've never seen any indication
that reducing the length of wire, or applying a mismatch, or even
using a step attenuator act any differently than one another.
All decrease the level in a "linear" manner. IE: all three
treat noise no differently than any other desired signal.
RF is RF is RF...

Comments from others on their
> experiences would be interesting. It is easy enough to try out out; just

> unless someone else wants to pick it up.

Due to receiver quirks, it's possible the radio might not sound quite
the same using the two methods, but still, a 20 db decrease in
level is 20 db no matter how it is done. It will decrease noise
and desired signals in an equal manner as far as the
fundamental frequency is concerned. So my vote is yes.
They do the same at the end of the day.
Most radios have way more level than they need.
I've never seen *any* antenna that could magically weed noise
from desired RF without making use of a directive pattern.
As an example, many claim full size loops are quieter than
dipoles on the lower HF bands.
But I've never seen it myself. The only way an antenna can receive
less noise, and not reduce the level of the desired signal is
with directive gain/nulls. And if a certain noise signal say to the
south is reduced on a loop vs dipole, you can bet a desired signal
in the same direction and polarity will be reduced also.
There is no free lunch.
Of course, if you were in the high mountains and had corona
buildup ala HCJB, a loop may well be quieter than a dipole, but I
consider that a rare case, and not applicable to most average
hams.
In most all cases, the receiver just sees a 20 db drop in level.
It has no idea how it came about, and the end result should

be the same as long as directive gain or nulls don't come into
play.
MK

Thanks for your comments. Do you believe there is any technical basis for
claims that vertical antennas are noisier than horizontal antennas due to
more man made noise being created with vertical polarization? This makes
inverted V an ideal compromise?

Yes and no.. Just depends on the polarity of the noise.
On 40m, I've had the luxury of being able to run both full
size dipoles, and a full size elevated ground plane
at the same time. Myself, I don't consider a vertical any
noisier than a horizontal antenna as long as the noise
source does not match the polarity of the antenna in use.
I've seen cases where local power line noise was just
as bad horizontal as it was vertical.
I'm in a big city, and I've never found noise to be any
great problem on a vertical. Overall, it was no worse
than the dipole.
And even if the background noise is a bit higher on the
vertical for some reason, the advantages of it's pattern
override and swamp any problems the noise might cause.
IE: say I'm on 40m at night working VK land.
The dipole shows a resting noise level of S 5 as an
example.
Say the vertical shows noise at S7.
Being the usual advantage of the vertical to VK land
was 4 S units vs the dipole, the 2 unit increase in
noise becomes a non issue. The higher level
of the desired signal swamps the extra noise.
Now , if you had a strong noise source that was vertical
with little horizontal componant, it could be more
of a problem if it happens to override even the large
increase in desired signal, but that not a fault of the
antennas. They are just acting as they should.
IE: the elevated GP did much better at the low
elevations vs the dipole. So it's going to be natural
that it also receives local noise farther away than
the dipole. But I don't consider this as a "fault".
It's just acting as it should. RF is RF is RF.
I can tell you, if I'm working VK or EU and have
the choice of the dipole, or the GP, I'd take the GP
any day of the week, extra noise or not.
It will be rare for the noise pickup to exceed the
increase of the desired signal.

So basically, I consider the vertical vs dipole noise
issue, a non issue.. :/

Keith Dysart wrote:

clip text.....

After considerable thought, I think the math you presented above is for one of two cases of reflective waves, the reflection from a higher impedance load. When the load is less than the Zo of the line, the currents add but voltages subtract. Right?

I don't think so.
Vt = Vf + Vr, It = If - Ir, Vf = If * Z0 and Vr = Ir * Z0 are the
fundamental
equations defining forward and reverse waves.

Perhaps you arrive at two choices because sometimes Vr and Ir
are negative, which after simplification appears to give an
alternate form?

The end result is the same for both cases.

This is good. If you chase the signs, though, I think you will find
that there is only one case.

We probably should not toss Power into the mix until agreement
is reached on this. Power is fraught with issues which seriously
confuse some.

...Keith

I can see that I need to further explain.

My analysis always begins with the source because the first formation of the wave comes from the source, then travels through the transmission line system. The source defines the wave only until the wave reaches any discontinuity(s) or the line end. Thereafter, discontinuities and end conditions define the system,.

Why might I say that? Initiation of the wave at the source results in a sine wave with the impedance of the transmission line, and the power and frequency of the source. This is a steady state condition until the first discontinuity or reflection point is reached by the traveling wave. Each successive reflection point (discontinuity) reflects power which travels back to the source and changes the feed point impedance conditions. The most distant possible reflection point is the end of the transmission line (ignoring reflections which might occur on the antenna) and might be an open circuit, a reactive resistance, or a short circuit. Any power reflected from the end will change the measured impedance found at any point on the transmission line all the

way back to the source, and will define the steady state conditions of the system.

If we accept that the steady state conditions are defined by the load, then we should examine the conditions on the source side of the load, assuming it is the end of the transmission line. The forward wave spawns the reflective wave in one of two ways, one way of load resistance higher than line impedance, and a second way of load resistance lower than line impedance. In both cases the power of both forward and reflective wave add, but the voltages and currents both add and subtract. (Cecil explained it very well in his follow up postings. Thanks Cecil.) I presented the power equations to illustrate the two conditions.

It is convenient that both cases result in the same math for the directional watt meter.

I'd still suggest that you have the cart and the horse backwards.

The math came first and that is why all the example cases turn out
to be consistent with the math.

And just for completeness...
The fundamental equations also work when:
- the signal is not sinusoidal, e.g. pulse, step, square, ...
- rather than a load at one end, there is a source at each end
- the sources at each end produce different arbitrary functions

- the arbitrary functions at each end are DC sources
It is highly instructive to compute the forward and reverse
voltage and current (and then power) for a line with the same
DC voltage applied to each end.

In another thread, "Calculating a (fictitious) phase shift;
was : Loading Colis", David Ryeburn has provided the
arithmetic for the general case which includes the
following expression:

-j*(Z_2)*cot(alpha + beta) = -j*(Z_1)*cot(alpha)

"alpha" is the length of the open line
"beta" is the "phase shift" at the joint
"Z_2" is the impedance of the open line
"Z_1" is the impedance of the driven line

It can be seen, as noted by Cecil, that beta
will be the same if the impedances of the two
lines are scaled proportionally.

But beta is dependant not only on the two
impedances, but also on the length of the
open line.

There are no simple relationships here.

It does not seem to be a concept that is
particularly useful for the solving of problems.

Looks like you haven't thought it through. If one wants to create a shortened dual-Z0 stub with equal lengths of each section of Z0High and Z0Low, here is the corresponding chart for different ratios of Z0High/Z0Low.

http://www.w5dxp.com/DualZ0.gif

As an example, one can create an electrical 1/4WL stub that is 1/3 the normal physical length by using 600 ohm line and 50 ohm line.

There are many ways to create the impedances
for matching, each with different advantages. As
you point out, one of the benefits of using two
different impedance lines is a reduction in material,
though, you could go all the way to just using
a lumped capacitor and save even more.

This reality, however, does not demonstrate any
value for the *concept* of phase shift at a
discontinuity. For the concept to be useful it
should facilitate understanding or problem
solving. As far as I can tell, you always solve
the problem in the conventional way (change
the angle on the Smith chart, un-normalize
the impedance, re-normalize the impedance
to the new Z0, measure the angle to get to
the desired impedance) and then work out
the "phase shift" at the discontinuity. It sure
looks like additional work that adds no value
since the important and useful information
has already been derived before computing the
"phase shift".

As such, I declare it "not particularly useful".

Cecil,

So how do you make that 12:1 connection, say 50 ohm coax to 600 ohm open line? Do you s'pose the connection bits add any phase shift all by themselves? Do you have a model for that extra phase shift?

Interesting! The important thing is to get answers that agree with
our experiments.

I have done some computations for DC voltage applied to transmission
lines. The real surprise for me came when I realized that transmission
line impedance could be expressed as a function of capacitance and the
wave velocity. Z0 = 1/cC where c is the velocity of the wave and C is
the capacitance of the transmission line per unit length.

3285. Re: Standing Wave Phase in Loaded Mobile Antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-13 17:00:17 UTC
From: Cecil Moore <nospam@w5dxp.com>
Message-ID: <Cyd8j.3951$Vq.1529@nlpi061.nbdc.sbc.com>
Source record: 31492

Keith Dysart wrote:
> This reality, however, does not demonstrate any
> value for the *concept* of phase shift at a
> discontinuity.

It may indeed have little value for stubs. But
for loaded mobile antennas the value is obvious.

The value is that it explains the phase shift
through a loading coil in a loaded mobile
antenna and the phase shift at the coil to
stinger junction. Using dual-Z0 transmission
line stubs we are ready to understand loaded
mobile antennas, the phase shift through the
loading coil, and the "missing degrees" at the
coil to stinger junction.

According to Dr. Corum, my 75m Texas Bugcatcher
coil has a Z0 of ~4000 and a VF of ~0.02.

The stinger has a Z0 in the ballpark of 400 ohms
and a VF close to 1.0

Knowing what we know about a dual-Z0 1/4WL stub,
we can now use that knowledge to analyze a base-
loaded mobile antenna with coil and stinger.

---Z0=4000 ohm coil---+---10 deg 400 ohm stinger

Now it's a piece of cake. How many degrees of
loading coil do we need to make the configuration
90 electrical degrees long?

Arctan((400/4000)*cot(10)) = ~30 degrees

What is the impedance at the coil to stinger
junction?

400*cot(10) = ~ -j2300 ohms

What is the phase shift at the coil to stinger
junction?

90 - 30 - 10 = ~50 degrees

I stumbled upon the dual-Z0 stub idea in trying to
understand the phase shifts and delays in a loaded
mobile antenna. The same general principles apply.

Using traveling-wave current to measure the delay
through my Texas Bugcatcher coil agreed within 15%
with these calculated values.

One side said the coil had to make up the missing 80
degrees of antenna that necessarily had to be there
with a 10 degree stinger. This side did not understand
the phase shift at the coil to stinger junction.

The other side said the coil, like a lumped inductor,
has ~zero phase shift through it. This side did not
understand the limitations of the lumped circuit
model.

The delay through a coil is what it measures and
calculates to be within a certain accuracy. It is not
80 degrees and it is not ~zero degrees.

I am in the middle of a brain fog/block.

I am attempting to get an equation to obtain the cotangent of x (or 10 in the above.) I HAVE DONE THIS BEFORE-got something wrong here ...

(1/tan(10)) = 5.67128

and (400*(1/tan(10)) = 2268.51273

There is no "built in" cotan function on my ti-86, ti-83, etc.

Help me out Cecil, anyone?

Regards,
JS

>

Things to consider:

Vertical antenna is "looking" at signals close to ground and at vertical polarization.

Most of the local noise (fluorescent lights, noisy dimmers, etc.) is "all" polarized but when in the "view" of the antenna, it will be significantly stronger.

Horizontal antenna might just "look" over it or when oriented with null in the pattern at the noise source, "ignore" it.

In the case of 160m vs. 40m dipole less noise case, it could be also that the ends (and rest of the antenna) of the 40m dipole are farther away from the local noise source and with mismatch could give improved S/N reception.

With atmospheric noise, the best remedy is the directional array that reduces the amount of the degrees of noise from undesired directions. Equatorial noise is major culprit.

Good tool to fight noise is the noise limiter - phasing unit.

Your continued BPL cheerleading has nothing to do with antennas, "John".
It doesn't seem that the information you provide is all that accurate
either. The ARRL web page featured the following article recently:

quote

FCC 'Admonishes' Ambient Over BPL Issues
ARRL Web Extra courtesy of the American Radio Relay League
Newington, CT, November 14th, 2007 ï¿½

The FCC, in a letter to Yehuda Cern, Chief Engineer for Ambient
Corporation, concluded their investigation into whether Ambient's BPL
operation caused "harmful
interference" to Amateur Radio stations in Briarcliff Manor, New York.
The Commission found that "Ambient's
BPL operation has violated the radiated emission limits of Section
15.109" of the FCC Rules "and the terms of its
experimental license, call sign WD2XEQ." The FCC's letter went on to say
that "we hereby admonish Ambient." No findings were
made, however, as to whether or not the system actually caused
interference to Amateur Radio, and the Enforcement Bureau left
open the issue of future experimental BPL operations at Briarcliff Manor.
Since Ambient's Briarcliff Manor facility is operating under an
experimental license, the FCC says Ambient "is subject to the operating
conditions contained on its license. Condition 4 of its license requires
that Ambient file a progress report six months from the date of
the grant. Additionally, Condition 5 provides that the progress report

'... should include, but is not limited to, a description of measurements and results demonstrating compliance...' with the radiated emissions limits of Section 15.109."

Ambient submitted a progress report on February 5th, 2007. The report indicated that Ambient "[h]as notched out its signals on the Amateur Radio bands, demonstrating significant advancements..." but the report did not address Condition 5, according to the FCC.

FCC Responds to Ambient

The FCC's Spectrum Enforcement Division sent letters to Ambient in March and May 2007, directing Ambient to "provide the results of any measurements made prior to the filing of its February 5, 2007 report to demonstrate compliance with the radiated emission limits of Section 15.109." The Division also directed Ambient to "submit a follow-up report confirming compliance once it had completed any necessary system modifications."

Ambient's attorneys filed responses to the FCC's March and May letters in June. Ambient's response, the FCC said, indicated that Ambient "had made compliance measurements as required by the Division." Ambient's response further stated that they had found "an older, first generation BPL unit in its network was malfunctioning, causing the device to exceed the applicable Section 15.109 emission limits," and that it "immediately took the equipment out of service." Ambient, the FCC said, "indicated that [they] would soon replace the remaining first generation equipment in its network with newer equipment."

In August, Ambient told the FCC that it has replaced all its first generation BPL equipment with second generation equipment. The FCC's letter to Ambient goes on to say that Ambient has completed and submitted results of on-site testing that demonstrates compliance with the Commission's regulations. In the time since Ambient replaced all their equipment, "neither Ambient or the [Spectrum Enforcement] Division has received complaints indicating continuing interference to Amateur operations from Ambient's BPL system," the FCC's letter said. The FCC made no findings about the interference that had been previously reported, however, nor did the Commission undertake any on-site investigation or inspection of the facility at Briarcliff Manor.

The FCC found that Ambient's BPL operation in Briarcliff Manor "has operated in violation of Section 15.109 of the Commission's Rules. Accordingly, we admonish Ambient for violating Section 15.109 of the Commission's Rules and the terms of its experimental license, call sign WD2XEQ." The FCC cautioned Ambient that any violations of future license provisions "may result in additional sanctions."

ARRL Filed Numerous Complaints with FCC Regarding Ambient's Briarcliff Manor Operation

ARRL first filed a complaint with FCC concerning the radiated emission violations at Briarcliff Manor on October 12th, 2004. Subsequent complaints were filed on December 17th, 2004; January 7th, 2005; March 17th, 2005; January 6th, 2006; March 29th, 2006,

and June 1st, 2007 each of which reported ongoing harmful interference caused by the unlawful operation of Ambient's BPL system at Briarcliff Manor. The complaints included technical reports on the result of tests conducted by ARRL staff. Each of the complaints requested that the Ambient system be required to cease operation immediately. The FCC took no action on any of these complaints, and it did not address any of them in its letter to Ambient.
Still before the Commission is the question of whether or not Ambient's experimental authorization should be renewed for a further period. Ambient has had an experimental authorization in Westchester County, NY since June of 2002. The most recent experimental authorization expired August 1st, 2007. On July 24th, Ambient filed an application to extend their authorization for an additional two-year period. ARRL filed an informal objection to that application on July 25th, arguing that Ambient should be held to the same standard as the other BPL companies which are subject to the rules governing BPL, such as inclusion of the BPL system in the public database, so that victims of BPL interference can determine the source of it.
ARRL Chief Executive Officer David Sumner, K1ZZ, said, "It is gratifying that the FCC finally has recognized that Ambient's BPL operation in Briarcliff Manor violated both the FCC rules and the terms of its experimental license, has made these violations a matter of public record and has admonished Ambient; however, this action comes three years and one month after the ARRL first brought Ambient's violations to the Commission's attention. This is hardly the speedy resolution that the Commission has promised, and to which its licensees are entitled."
ARRL General Counsel Chris Imlay, W3KD, concurred with Sumner, saying "The FCC's admonishment to Ambient was 'too little, too late' from the FCC's Enforcement Bureau. It continues the disappointing inaction that we have come to expect from FCC in addressing blatant cases of harmful interference. Must Amateur Radio operators wait more than three years for some relief after filing legitimate complaints of harmful interference? The FCC has consistently refused to even acknowledge, much less investigate, the complaints of harmful interference at Briarcliff Manor, because it wants no bad news about BPL."

Interesting you place me so firmly on the "cheer leading" side ...

You are an idiot. If what those panicking here are correct, it has
everything to do with antennas! They are the only part of our equipment
which will suffer the onslaught of this "naughty interference!"

If BPL comes to pass, and there are no major problems--only sporadic
stuff ... well, you know ...

Hi Roger,

This last round has piqued my interest when we dipped into DC. Those
"formulas" would lead us to a DC wave velocity?

As I have said before, I am using whatever definition is used, for example, by Haliday and Resnick when they talk about power. I am not able to inquire as to what exact definition they use. All I know is when you say that energy is "transferring" in a transmission line, and then try to use that statement as proof that "power is moving" in a transmission line, you have the wrong idea about transfer of energy. That is precisely where this discussion originated, but I'm sure that you will disagree - as it is your nature to be highly disagreeable on this subject.

I recently tried, on this newsgroup, to explain to Richard Harrison that power does *NOT* move in a transmission line. Richard thinks that power does move as do most of my engineering textbooks and the IEEE. Johnson, Ramo, and Whinnery all talk about "power flow". Because it was hairlipping you, I removed any reference to "power flow" from my magazine article in support of your concept that power does not flow.

I have *NEVER* said "power is moving", at least not in this century. That is just your straw man raising its ugly head yet once again. Jim, when you force yourself to bear false witness about what I have said, you are essentially giving up whatever integrity and ethics you ever had. Why you have to resort to such underhanded unfair techniques speaks volumes.

Do you imagine that the caviat "not in this century" might make the
statement at least partially true?

> That is just your straw man raising its ugly head
> yet once again.

Was it not raised when you brought the definition of 'transfer' back
into the discussion - again this century?

Thinking back, one seldom heard terms like BDR or IP3 knocked around with respect to amateur receivers of that day. Sensitivity and selectivity was about it from an advertising standpoint. Amateurs were so determined to get hold of the new solid state or hybrid gear, that Collins S lines and Drake 4 lines with better specs than the new gear could be had outrageously cheap.

Yes.

> "Z_2" is the impedance of the open line
> "Z_1" is the impedance of the driven line

Backwards. Z_1 is the characteristic impedance of the open-circuited line
(100 ohms, in some of the examples previously discussed). Z_2 is the
characteristic impedance of line from the junction point back to the source
(600 ohms, in those examples).

I couldn't agree more. The angle alpha + beta is useful; the angle beta is
not. But I thought I would provide the formulas in an attempt to set things
straight.

Agreed. I've always liked capacitors better than transmission line segments. It takes a pretty crummy capacitor to have as low a Q as a transmission line section is likely to have. Even inductors are often better than transmission line segments. But W5DXP was trying to explain how a loaded mobile antenna worked (using transmission line concepts).

However, loaded mobile antennas presumably radiate, at least a little, and my analysis (and W5DXP's discussion of angle lengths of transmission lines and "phase shift" at their junction) is for *LOSSLESS* transmission lines. This makes me wonder.

Hi Dave -

We apparently each have our own approach for trying to quash the
spewing of claptrap science on r.r.a.a. I wish you better luck with
yours than I've had with mine.

In the 20th century, I did believe in power flow but you
convinced me that I was wrong and I changed my mind. I
have not believed in power flow during the 21st century.

I will keep bringing it up until you furnish the definition
that you are using for the word. That you absolutely refuse
to provide a definition means it is nothing but your gut
feeling about the matter.

The current conditions for a mobile antenna can be simulated
by a lossy transmission line made out of resistance wire.
The equations simply include the losses.

Reflected EM waves existing without energy is one of
the bigger claptrap science concepts on this newsgroup.

The energy content of a 1/2WL dipole is only about 20%
radiated which means that 80% of the energy doesn't
radiate, quite like a lossy transmission line.

For the record, you're the only one who has ever made any reference waves existing without energy on this newsgroup.

I doubt that you will understand it any better this time, but for the authoritative explanation of the concept (which you have always totally misconstrued), please refer to page 47 of Born and Wolf, 6th Edition. Under the heading "Total Reflection" you will find the following: "All the incident light is then reflected back into the first medium and we speak of total reflection. Nevertheless the electromagnetic field in the second medium does not disappear, only there is not longer a flow of energy across the boundary."

My message filter file for this newsgroup isn't devoid of entries
either. But I actually do enjoy much of what Cecil has to say. I
always have. In a perfect world he would spare us the nonsense. But
there really is no such thing as perfection, is there.

So as a New Years resolution I will try not to feed any trolls. :-)

Thank you,

ac6xg

Can you expand on the 20%, 80% above.

For convenience assuming the dipole is lossless, it seems
to me that after the transmitter is turned on, some of the
energy is stored in the antenna, but once the antenna
is charged, all the energy entering the antenna is radiated
until the transmitter is turned off, after which the energy
stored in the antenna is radiated until the antenna stores
no energy.

So everything that goes in to the antenna is radiated.

...Keith

Geesh, I had it, but sure didn't look right ... a walk around the block
and letting things go put all back to right ...

CoT(10) = (1/tan(10))

damn ... moments like these are humbling ...

Sometimes my progress forward is "inversely proportional" to the energy
I apply ... ;-)

Hi Richard,

Here are two links to pages that cover the derivation of the formula Zo
= 1/cC and much more.

http://www.speedingedge.com/PDF-Files/BTS002_Characteristic_Impedance.pdf
http://www.ece.uci.edu/docs/hspice/hspice_2001_2-269.html

Here is the way I proposed to Kevin Schmidt nearly seven years ago after seeing him use the formula on a web page:

ASSUME:
1) An electrical wave travels at the speed of light, c
2) A 'perfect' voltage source without impedance, V
3) A 'perfect' transmission line having no resistance but uniform capacitance per unit length, C

CONDITIONS AND SOLUTION
The perfect voltage source has one terminal connected to the transmission line prior to beginning the experiment. The experiment begins by connecting the second terminal to the transmission line. The voltage source drives an electrical wave down the transmission line at the speed of light. Because of the limitation of speed, the wave travels in the shape of a square wave containing all frequencies required to create a square wave.

The square wave travels down the transmission line at the speed of light (c). After time (T), the wave has traveled distance cT down the transmission line, and has charged the distributed capacity CcT of the line to voltage V over that distance. The total charge Q on the distributed capacitor is VCcT.

Current (I) is expressed as charge Q per unit time. Therefore the current into the transmission line can be expressed as

I = Q/T =
VCcT / T = VCc

Impedance (Zo) is the ratio of voltage (V) to current (I). Therefore the impedance can be expressed as

Zo = V / I =
V / VCc = 1/Cc

We can generalize this by using the velocity of the electrical wave rather than the speed of light, which allows the formula to be applied to transmission line with velocities slower than the speed of light.

Of course, only the wave front and wave end of a DC wave can be measured to have a velocity.

Hi Roger,

However, none of what you respond with actually gives a DC wave
velocity. At a stretch, it is a transient with the potential of an
infinite number of waves (which could suffer dispersion from the
line's frequency characteristics making for an infinite number of
velocities). The infinite is a trivial observation in the scheme of
things when we return to DC.

Attaching a battery casts it into a role of AC generation (for however
long the transmission line takes to settle to an irresolvable
ringing). Discarding the term DC returns us to conventional
transmission line mechanics.

DC, in and of itself, has no wave velocity.

HTML enhanced text didn't help either. Some may shrug this off, but
browsers are the vectors of internet virii.

It's a logical conclusion is that if EM waves don't
transfer energy it's because they don't have any
energy to transfer.

> Nevertheless the electromagnetic field in
> the second medium does not disappear, only there is not longer a flow of

That's my argument, Jim. The electromagnetic field
that does not disappear is the fields that you say
never existed in the first place.

Before steady-state is reached, a considerable amount of
energy is stored in the standing waves following key-down
(your "charging" time). That energy stored in the standing
waves will not radiate until the source is disconnected,
e.g. after key-up.

A 1/2WL dipole is a standing-wave antenna. The energy
radiated from such an antenna is considerably less than
the energy stored in the standing-waves. The SWR on the
antenna is probably around 20:1.

Hey;

We were able to get the input impedance of the antenna down to 45 +
j15, which means an SWR of 1.6. Not too bad I think.

We used one of these http://www.cebik.com/trans/ser.html with a Z02 of
125 ohms.

Thanks everyone for your help, I'm sorry I didn't have time to
implement any of your much cooler suggestions!

Sean

For the model provided, R= 0, therefore we have a transmission line
consisting of superconductors. The speed at which steady state DC current is
injected into the model will equal the maximum speed of DC current in the
model. Although the electrons themselves will move very slowly, for each
coulomb injected in, one coulomb will be injected out at the same velocity
they were injected in (not to be confused with 'current' which is the number
of coulombs per second). If it were possible for the source to provide DC

current at c, then the DC current moves at c. The capacitance C can be any value and Zo has no meaning. The only model that works here is the one with a cardboard tube filled with ping pong balls, in this case with 0 distance between them.

Ah, but of so little importance because the model is not reality.

Well, been there--where a dollar REALLY is a DOLLAR!

I am sure it will pan out, those are SMALL devices, make sure your small soldering iron has a sharp tip!

I think you will like working with these devices. TV in my travel trailer has a ant preamp I constructed using a similar device.
I have a preamp on a fm radio DLM antenna I constructed (88-108mc), I kind of went crazy with 'em, for a period of time.

Becareful, they are voltage sensitive--don't exceed the rated B+, I power mine off 3 AA cells, 4.5V with quite satisfactory performance. Make sure you use the blocking cap between the MMIC and your front end, one on the front end too--with a couple of spike protecting diodes to protect the device is not a bad idea either--especially if the area you are in is prone to lightening or there are high power xmitters in the vicinity ...

Have any friends/family into electronics? Sell them the remaining devices and get some of your investment back. <devilish-grin>

I have paid 3-5 dollars a device ... back a couple of decades they were REALLY expensive.

Regards,
JS

I didn't place you there, "John", your posts have done that. You've
sung the praises of BPL more than a few times on this newsgroup.

> You are an idiot.

I'm a lot of things, "John". An idiot is not one of them.

> If what those panicking here are correct, it has
> everything to do with antennas!

No, John, the BPL posts aren't antenna related.

> They are the only part of our equipment
> which will suffer the onslaught of this "naughty interference!"

That's an absurd statement. I can erect all of the antennas I like and
none of them will suffer from BPL interference if they aren't connected
to a receiver.

> If BPL comes to pass, and there are no major problems--only sporadic
> stuff ... well, you know ...

Sporadic stuff? I know?

The FCC has tried to redefine Part 15. The Commission has tried to
state that an unlicensed service may interfere with a licensed service.
BPL is the electronic equivalent of air pollution.

I follow the principle, but I am not convinced that it is a
"considerable" amount of energy.

> A 1/2WL dipole is a standing-wave antenna. The energy

Consider a quarter wave-length of open circuited line connected
to a 100 W source. After 1/2 cycle it is fully charged. At 4 MHz
it stores 0.125E-6 J of energy. I can not see a mechanism
where a 1/2 wavelength antenna would store more than this
(SWR on the line would be inifinity, much worse than 20:1),
and it will be radiating 100 J/s. 0.125E-6 J is not much in a
system that is moving 100 J/s.

the OBVIOUS error is that the step when the second terminal is connected
DOES NOT travel down the line at c, it travels at some smaller percentage of

c given by the velocity factor of the line.

The second OBVIOUS error is the terminology 'DC wave'. you are measuring the propagation velocity of a step function. this is a well defined fields and waves 101 homework problem, not to be confused with the much more common 'sinusoidal stead state' solution that most other arguments on this group assume but don't understand.

That IS what I said. Think of the velocity as a moving wall, with the capacitor charged behind the wall, uncharged in front of the moving wall.

Be real. This experiment can be performed, and the DC switched as frequently as desired. How square the wave front will be depends upon real world factors.

Go to a transmission line characteristics table and use the formula to compare Zo, capacity per length, and line velocity. It will amaze you.

While R (ohmic resistance) is specified as zero, impedance is what we
are looking for. Impedance is the ratio of voltage to current.

So far as we know, the maximum velocity permitted in the universe is the
speed of light, which is the speed of electromagnetic disturbance. Here
we disturb the transmission line electromagnetically. Think of the
velocity of the wave front as a moving wall. Everything behind the
moving wall is charged to the applied voltage, everything in front is
uncharged. The ratio of voltage to current turns out to be a pure
resistance, dependent only on the capacity per length and wave velocity.

Before becoming too critical or skeptical, run the equation with the
characteristics from a few transmission lines. You will find that the
numbers are very close, but not exact. The published characteristics
are not carried out to many decimal places, and who knows to what
accuracy they were determined.

The step function from zero to DC contains a lot
of frequencies. I suspect photons are involved
at the leading edge of the DC pulse.

Only if the 100 W source is turned off after the first
1/2 cycle. If it is a constant power source and is not
turned off, the forward and reflected power in that stub
would increase without bounds except for I^2*R losses
and dielectric losses. Only when the power output of
the source equals the losses in the stub will steady-
state be reached and that could be when the forward
power is 1000 watts or more.

> I can not see a mechanism
> where a 1/2 wavelength antenna would store more than this

As I said above, if you have a constant power source,
the energy in that stub would increase without bounds.
The forward power is certainly not limited to the source
power. The source is only having to supply the losses in
the stub. The stub could be storing magnitudes more energy
than your calculation.

> (SWR on the line would be inifinity, much worse than 20:1),
> and it will be radiating 100 J/s. 0.125E-6 J is not much in a
> system that is moving 100 J/s.

As pointed out above, your logic is flawed. I estimate
that with 100 watts being fed into the dipole and 100
watts being radiated from the dipole, the forward power
is about 500 watts and the reflected power is about
400 watts at the feedpoint of the 1/2WL dipole.

There is also another flaw in your logic. You are equating
the length of time it takes to charge the stub to one
second so you are off by almost 10 magnitudes.

This is, of course, assuming that the constant power
source is seeing its designed-for impedance as it
would through a lossless matching network.

"Suspect" -- Perhaps like Inspector Clouseau?

Humour aside, for transmission lines you should
stick to charge, and distributed capacitance and
inductance. This model is aptly capable and has
no difficulties as the frequency drops so low that
it becomes indistinguishable from DC.

Why bother with photons? Only at the leading
edge, you say. What explains the rest?

Where is the energy stored? In the capacitance
and inductance. Why not use the tools that work?

Why try to force fit photons?

...Keith

Keith Dysart wrote:
> I follow the principle, but I am not convinced that it is a
> "considerable" amount of energy.

This is a follow up to my other reply. An example
closer to the 1/2WL dipole would be a Z0=600 ohm
1/4WL open stub made out of resistance wire such
that the input impedance is 50+j0 ohms. The resistance
wire simulates the radiation "loss" in a 1/2WL dipole.

100w---600 ohm 1/4WL stub---open

The 100w source sees a 50 ohm load because the stub
is made out of resistance wire.

What is the forward power on the stub at the feedpoint? _______

What is the reflected power on the stub at the feedpoint? _______

Stubs like this one are easily modeled with EZNEC.

Because it is impossible for electrons to move
fast enough to explain the measured results.
There is indeed a "DC" *wavefront* moving at
the speed of light adjusted for VF. Electrons
cannot move that fast. What is happening is
that fast photons are skipping from slow electron
to slow electron.

Hi Roger,

Take a deep breath, exhale, give what's above some more thought in
light of many objections.

Now, tells us just what significance any of this has in relation to
already well established line mechanics? It certainly isn't different
within the confines of its limitations if that is what you are trying
to impress upon the group. I suppose for a mental short-cut it has
some appeal, we get too many theories here based on approximations to
stricter math. One such example is when an equation of approximation
has forgotten the underlying |absolute value| and suddenly an inventor
arrives with a "new" theory that discovers uses for negative
solutions.

Further, there is nothing DC about it at all. DC is either static
(and in spite of Arthur's corruption of the term, that means no
movement whatever) or it is a constant unvarying current. A
succession of distributed capacitors rules unvarying current out (and
if it isn't already obvious, those unmentioned distributed inductors
in one of your links do too) - hence the step, hence the infinity of
waves, and from this, real world dispersion which kills the step
enough to make that varying current apparent enough so as to remove
all doubt.

If we look at a tree from the north side, and then look at the same tree from the south side, we have looked at only one tree but we have seen it from two perspectives.

Zo = sq. rt. L/C = 1/cC

Inductance can be described as L = 1/((c^2)*C) (inductance per length)

So is the energy stored in the inductance or in the capacitance.

Two ways of looking at the same tree.

The world's answer for energy shortage. Put in 100W and get 10 times
or more out. All courtesy of the modern miracle of superconduction
which is available TODAY!

But wait. That is not all. For the first 4 billion customers:

>As pointed out above, your logic is flawed. I estimate
>that with 100 watts being fed into the dipole and 100
>watts being radiated from the dipole, the forward power
>is about 500 watts and the reflected power is about

Our Soon-to-be-announced FORWARD WAVE DIPOLE will be arriving under
your Christmas tree in the future. Imagine applying only 100W to
enjoy the benefits of radiating 500W without the need for those
roasting hot linears that cost a fortune.

As a Bonus! Plug your rig into our patent pending energy stub that
requires less than 10W to power your rig, and here's a Christmas gift
you can take to the mountains in your backpack!

When was the last time your rig could radiate 500W for an hour from 10
AAA batteries? Better living through the bright promise of photons.
Look for our trademarked slogan:
"It's more than headlights in your eyes, dear."

Hi Richard,

The math seems to work, but if you have no use for it, disregard it. On the other hand, if another perspective of electro magnetics that conforms to traditional mathematics can provide additional insight, use it.

I am surprised at your criticism in using DC. To me, a square wave is DC for a short time period. Is the observation that a square wave can be described as a series of sine waves troubling to you? Perhaps the observation that a square wave might include waves of a frequency so high that they would not be confined in a normal transmission line is surprising or troubling to you?

My goal is to better understand electromagnetic phenomena. You have given some very astute insight many times in the past and thanks for that. Negative comment is equally valuable, but sometimes a little harder to swallow.

73, Roger, W7WKB

Right, the step function has a number of sinusoids associated with it
which are affected by Zo and that was already addressed. Richard's
challenge was to address the velocity of DC at steady state, after the
transients from the step died down.

Hi Roger,

This does not answer why TWO mathematics (both traditional) are
needed, especially since one is clearly an approximation of the other,
and yet offers no obvious advantage. I've already spoken to the
hazards of approximations being elevated to proof by well-meaning, but
slightly talented amateurs.

>I am surprised at your criticism in using DC. To me, a square wave is
>DC for a short time period.

This single statement, alone, is enough to be self-negating. You
could as easily call a car with a standard stick shift an automatic
between the times you use the clutch - but that won't sell cars, will
it?

>Is the observation that a square wave can
>be described as a series of sine waves troubling to you? Perhaps the
>observation that a square wave might include waves of a frequency so
>high that they would not be confined in a normal transmission line is
>surprising or troubling to you?

DC as sine waves is not a contradiction on the face of it? DC that
consists of waves of a frequency so high that it would not be confined
in a normal transmission line is very surprising, isn't it?

Would it surprise you to find your batteries in their packaging direct
from the store are radiating on the shelf? They are DC, are they not?
If the arguments of your sources works for an infinite line, they must
be equally true for an infinitesimal open line. When your headlights
are on, do they set off radar detectors in cars nearby because of the
high frequencies now associated with DC?

>My goal is to better understand electromagnetic phenomena. You have
>given some very astute insight many times in the past and thanks for
>that. Negative comment is equally valuable, but sometimes a little
>harder to swallow.

The pollution of terms such as DC to serve a metaphor that replaces conventional line mechanics is too shallow glass to attempt to quench any thirst.

The puzzle here is the insistence on hugging DC, when every element of all of your links could as easily substitute Stepped Wave and remove objections. The snake in the wood pile is once having fudged what DC means, it is only a sideways argument away from rendering the term DC useless. Is the term Stepped Wave (the convention) anathema for a leveraging the novel origination (the invention) of DC Wave?

Do photons also explain how sound can move
at a 1000 ft/s, while the air molecules barely
move at all?

No? Not clear then why they are needed for
electrons.

...Keith

Richard Clark wrote:
> The world's answer for energy shortage. Put in 100W and get 10 times
> or more out.

Why is that surprising? Put in 100 watts into a
battery bank for 10 hours and get 1000 watts out
for an hour. How does that answer the energy
shortage? Do you think it is a violation of the
conservation of energy principle for the charging
cycle to be longer than the discharge cycle?

If you run your transceiver on a previously charged
battery, the steady-state power output of the battery
is an *infinite* number of times the steady-state
power input to the battery. Why do you think that's
strange?

The standing-wave energy is stored in the stub all
during steady-state. That stored energy is only
available to be output *after* steady-state. When the
power input to the standing-wave antenna is removed,
the power output from the standing wave is infinitely
greater than the input power for a few nanoseconds.

After the charging energy is removed from a capacitor,
the stored energy is still available. Why do you
think that is strange?

Anyone who has ever tried to send a DC pulse down a long
transmission line has seen AC ringing at the other end.

No, mechanical longitudinal waves are well understood.
It is impossible for them to achieve the speed of light.

> No? Not clear then why they are needed for
> electrons.

Do you think electrons support mechanical waves?
The fields of TEM waves consist of photons traveling
at the speed of light.

Hi Thierry

I dont know enough about "mode" terminology to answer your question about "analog" or "digital". I have been actively involved with trying to build an antenna for receiving signals from NOAA polar orbiting satellites at 137 MHz and from AMC-4 geostationary satellite.at 4 GHz.
I assume you refer to your buying a Receiver when you wrote Receive.
The images from the polar orbiting NOAA satellites are sent down at both 137 MHZ and at 1.7 GHz. The 1.7 MHz signals require a high gain antenna that needs to track the satellite.

The GOES, S band and the POES HRPT, L band systems cost thousands of dollars since they include high gain antennas. If you are thinking about spending thousands on a "receiver + antenna" I think you would already be well informed about what to buy. I'll assume you are considering buying an antenna and receiver for 137 APT image reception.

I recommend the R2FX receiver http://www.geo-web.org.uk/shop.html for 137 MHz imaging. It is designed to receive FM signals. Any 137 MHz FM receiver will work for receiving APT images in the 137 MHz band, but very few will provide adequate signal to produce good images.
The Quad Helix is considered to be the ideal APT antenna. Dartcom http://www.geo-web.org.uk/shop.html has high quality Quad Helix antennas for sale at about $350.00.

If you have interest in building your own antenna for 137 MHz APT imaging, I can show you how to build one that performs better than a Quad Helix.for less than $20.00.

No, because those are called Phonons.

>No? Not clear then why they are needed for
>electrons.

Phonons and Photons both interact with Electrons as well as with each
other.

Following Cecil's fluff isn't very productive.

Source record: 31438

This general discussion sounds a lot like a description of a traditional TDR system using a step function. You should be able to find quite a bit of information about this process on the web.

A number of relationships among delay, Z0, velocity factor, and L and C per unit length are quite useful, and I've used them for many years. For example, a transmission line which is short in terms of wavelength at the highest frequency of interest (related to the rise time when dealing with step functions) can often be modeled with reasonable accuracy as a lumped L or pi network. The values of the lumped components can easily be calculated from the equations relating delay, Z0, L per unit length, and C per unit length.

Strictly speaking, DC describes only the condition when a steady value has existed for an infinite length of time. But a frequency spectrum of finite width also requires a signal which has been unchanging (except for periodic variation) for an infinite time. In both cases, we can approximate the condition with adequate accuracy without having to wait an infinite length of time. In the case of a step response, we wait until all the aberrations have settled, after which the response is for practical purposes the DC response. People used to frequency domain analysis having trouble with the concept of DC characteristics and responses can often get around the difficulty by looking at DC as a limiting case of low frequency.

I don't know if it's relevant to the discussion, but the velocity factor of many transmission lines is a function of frequency. A classic example is microstrip line, which exhibits this dispersive property because the fractions of field in the air and dielectric changes with frequency. Coaxial line, however, isn't dispersive (assuming that the dielectric constant of the insulator doesn't change with frequency) because the field is entirely in the dielectric. It will, therefore, exhibit a constant velocity factor down to an arbitrarily low frequency -- to DC, you might say. Waveguides, however, are generally dispersive for other reasons despite the air dielectric. The shape of the step response of a dispersive line is very distinctive, and is easily recognized by someone accustomed to doing time domain analysis.

There seems to be a constant search on this newsgroup for amazing new principles, and "discoveries" are constantly being made by misinterpretation and partial understanding of very well established principles. I sense that happening here. Anyone who's really interested in gaining a deeper understanding of transmission line principles and operation can benefit from a bit of study of time domain reflectometry and other time domain applications. All the fundamental rules are

exactly the same, but the practical manifestations are different enough that it can give you a whole new level of understanding.

Dr. Corum's formulas indicate that the velocity factor
of large coils is also a function of frequency.

yes. because its WRONG. you have made an assumption that is not realistic
for any transmission line. There is no way a transmission line can have a
velocity factor of 1.0, just can't happen... all the equations fall apart
and become meaningless at that point. there is a reason for the velocity
factor, or beta, depending on which you prefer. learn it, and use it
properly, and it will serve you well.

Roger the impedance is zero because the current is steady state DC. F = 0,

Zo = 0 -j*2*pi*0*C =0

It was already stated that we should ignore the wavefront of the step
function. What we are left with is steady state. So impedance is not what
'we' are looking for.

(I sure am learning a lot about antennas and transmission lines here)

I'm glad to hear that. Does the new knowledge include a way to tell the four black boxes apart at one steady state frequency, or how many "electrical degrees" each one contains?

Yes, I am learning a lot also.

Well, I did not say we should ignore the wave front, just the opposite.
The wave front gives us the time marker so that velocity has meaning
in relationship to a length of transmission line.

Roy is giving good advice to study time domain reflectometry. One
reference I looked at used different pulse widths to examine for faults
at different distances. That makes sense to me.

Where did you get the formula for Zo that resulted in a zero impedance?

> thanks
> Thierry

I don't think you really do need to know this ...

What you need to know is to buy a receiver capable of decoding digital,
that is where EVERYTHING is going to end up ... only ancient equipment
is still using analog--what holds am (mw) broadcast and fm broadcast to
analog is the sheer logistics in everyone upgrading to digital--along
with the broadcasters themselves.

If amateur radio was still a viable hobby (in terms of numbers) it would
also be making the jump to digital ... however, in vhf and beyond you
will find digital savvy amateurs.

Make sure the sat/weather receiver is able to do flash upgrades to its
firmware, otherwise it is liable to be obsolete before you can get it
out of the box ...

No special antennas are needed to "jump" between analog and digital ...
the same antenna will work for both ...

I'd suggest that this is an inaccurate interpretation.
For an ideal line we have

Z0 = sqrt(L/C)
and
velocity = 1/sqrt(LC)

These are the fundamental equations based on the
charactistics (distributed L and C) of the line.

These equations can be manipulated to yield
Z0 = 1/(velocity * C)
and
Z0 = velocity * L

But Z0 continues to exist regardless of the signal
being applied.

Think of the "velocity" as the velocity at which a
perturbation to the signal propagates down the
line.

When you turn on the constant voltage, the step
propagates down the line at "velocity", when you
change the voltage, the new step propagates at
"velocity". Over any region of the line where
the signal has a constant amplitude, it will
be difficult to discern this "velocity" but on
other regions of the line where a change is

present, it will be possible.

So if there are no perturbations, the "velocity"
can not be observed, but it would a mistake
to think that it goes away (or that Z0 does).

The original problem statement discused -j567 as
an impedance. This is implicitly frequency dependant.

The Smith chart is normalized for impedance
and frequency.

When allowed to excite the black boxes with different
signals there are many ways to determine an internal
equivalent circuit. The question here was did the various
ways of making -j567 affect the results for sinusoidal
single frequency excitation.

The smith chart is normalized *only* by Zo.

Tell me, how is Zo related to frequency :-) Or better, tell me how the smith
chart is normalized by frequency?

>

In the example, -j567 was merely due to a phase change due to the abrupt
impedance discontinuity. You are the one who suggested putting things in
black boxes. I suppose you could devise ways to phase shifts due to -j567 in
black boxes but I will have to leave that to you since you are the one who
brought up the idea.

Do you suggest that there is no phase shift?

Then how do you explain the smith chart results?

> Not if I change the capacitance.

Each of the different ways mentioned for obtaining -j567
will produce a different impedance if the frequency is
changed. They were all frequency dependant.

> > The Smith chart is normalized for impedance
> > and frequency.
>
> The smith chart is normalized *only* by Zo.
>
> Tell me, how is Zo related to frequency :-)

> Or better, tell me how the smith
> chart is normalized by frequency?

Everything is done in terms of degrees along a wave.
This implicitly normalizes for frequency.

> > When allowed to excite the black boxes with different
> > signals there are many ways to determine an internal
> > equivalent circuit. The question here was did the various

> black boxes. I suppose you could devise ways to phase shifts due to -j567 in
> black boxes but I will have to leave that to you since you are the one who
> brought up the idea.

Several ways were mentioned for obtaining the -j567:
a capacitor, some length of 100 ohm line, a different

length of 600 ohm line. Regardless of how the -j567
impedance is obtained, the same input impedance
to the 600 ohm line results. And yet each appears
to have a different phase shift occurring at the terminals.

Putting things in black boxes is a thought experiment
which helps isolate which aspects are important.
Any box containing a circuit which produces -j567
at the terminals will result in exactly the same
impedance at the input to the 600 ohm line, so
clearly -j567 is important.

Is the "phase shift" at the discontinuity important
when the results can be determined without knowing
the value. In fact, the "phase shift", in all the
examples, was computed last, after all the results
were known. How important can it be?

> Do you suggest that there is no phase shift?

I suggest that there is no value in thinking about
the "phase shift" at the discontinuity (which depending
on the black box chosen might not be present), and
merely think about the results of connecting the
-j567 impedance to the 600 ohm line.

> Then how do you explain the smith chart results?

Starting with the 100 ohm line, the normalized
input impedance was computed using the Smith
chart. This impedance was denormalized and then
renormalized to the 600 ohm. The new value was
plotted on a new Smith chart (the chart normalized
to 600 ohms) and the length of the 600 ohm line
was determined. The two lines have lengths, call
them Z1len and Z2len. 90 - (Z1len + Z2len) will
give a number which Cecil/you have called the
"phase shift" at the discontinuity. Alternatively,
it is just what happens when -j567 is attached
to the appropriate length of 600 ohm line.

Cecil did not answer the question, so I will
pose it again. If knowing the phase shift at
the terminals of the black box is important,
and you can not know it without knowing the
internals of the box, given a black box of
unknown internals but told that its terminals
present -j567 at the frequency of interest,
would you refuse to calculate the length
of 600 ohm line needed to produce 0 ohms?

I suggest that there is no need to refuse
since the only information that is required

is -j567. Whether the box achieves this with
600 ohm line ("no phase shift"), 100 ohm
line ("some phase shift"), a capacitor or
some other technique is irrelevant.

...Keith

There was no ignorance nor any bull exhibited, "John". You must feel
that snipping the material vindicates your view. Such material is
easily replaced. I outlined my case and your response was to snip and
call names.

> Heil:
>
> Are you just wrong about everything about amateur radio, or does this

Feel free to attempt to refute anything I've written.

> I truly pity you, moron ...

I don't believe that statement any more than I believe your schpiel about BPL. You just don't have the courage of your convictions. You remain anonymous and begin name calling rather than debating what you yourself brought up.

There is a specific recognized usage of the term "normalize" when referring
to a smith chart. It does not involve frequency.

The value is more obvious when applying the concept to a loaded whip
antenna.

But you have 10 degrees of 100 ohm line and you have 43 degrees of 600 ohm line.

You also have resonance at 1/4W.

For 1/4W resonance you must have 90 degrees.

What happened to the missing 37 degrees?

If some do not care, then I agree that it is not important. It comes out of a black box for all they care.

Others find it fascinating what nature does in order to keep following its rules. I would never go through all the trouble to calculate this using math but with the smith chart calculating for you, information like this jumps out at you. When it does, many people yawn, others relate it to how antennas with loading coils work and reveals one reason why Dr. Corum had to make corrections for the true behavior of coils.

Sure, you can do anything you like. But can you tell the boxes apart by measuring at just one frequency (the one at which their impedances are the same)? Do they have the same or different numbers of "electrical degrees" at that frequency?

The fourth box was my proposal, a box containing a capacitor with the same reactance as the contents of the other boxes, and which I claimed couldn't be distinguished from the others.

Strange, for the 600/100/10 degree I get:

Arctan(100\600)*(1/tan(10)) = 53.6635

for 300/50/10 degree:

Arctan(50\300)*(1/tan(10)) = 53.6635

and for 600/50/10 degree:

Arctan(50\600)*(1/tan(10)) = 27.0160

What am I missing here?

Arctan(50\600)*(tan(80)) still equ 27.0160

Don't tell me the calc is on the fritz!

Regards,
JS

I also eventually agreed that I went too far to suggest one *could* tell the differences. I could go back and find the post where I made that retraction but it might take some time. It was a 'by the way' sort of thing; it seemed to be almost corroborative but it was definitely was incorrect although not very important in the overall discussion. Thank you for having corrected me before. I thought I previously had submitted to the lashes of the whoop haung (or whatever they call that thing at ARRL that you use to punish hams).

Thanks, I had missed that posting. Did you also conclude, then, that all the boxes contain the same number of "electrical degrees"?

Hi,

I bought a used MFJ1734 (2m/70cm) on glass antenne without
installation instructions.
This I found at mods.dk but I'm confused on how to mount the little 6
inch ground plane hook.

Is there anyone who can mail me a picture of this ?

actually it is what you are looking for, you have just, again,
misinterpreted the results. in the DC case you have to remember that not
only is f=0, but wavelenght is infinite. so a shorted stub of any length of
transmission line appears to be 0% of a wavelength. using the normal
equations, or smith chart, to transform the impedance at the far end of the
line to the connection point will result in exactly the same impedance at
the connection point as is at the far end. so feed a DC current into a
shorted line of any length and in steady state you get infinite
current(assuming no loss in the line of course), use an open line and you
get zero current. put a resistive load out there and you see the load
resistance. it all works, you just have to know what to look for and just
what the conditions you have specified really mean.

as far as probing the 'black box' with varying frequencies or pulses to see
what is in it, you again must more clearly state the conditions. when it
was suggested that you could stick all the different circuits you used to
obtain the same impedance in a box and it was added to that a single
capacitor would look the same, the implicit assumption is that you are ONLY
going to examine the circuits in sinusoidal steady state at a single
frequency. that is the ONLY case where that type of replacement is valid.
if you allow transients or multiple frequencies than you can not substitute
a 'black box' for the unknown circuit. refer to any book from a circuits
101 course for the full analysis.

Simplicity itself. Electrons are charged. Like charges
repel. Move an electron and the next electron will tend
to move away.

> The fields of TEM waves consist of photons traveling
> at the speed of light.

I've been told that near the antenna, there are just
varying electric and magnetic fields and that some
distance from the antenna the electro-magnetic
wave forms. How does the varying field turn into a
photon? At what point? Where does the simply
varying field end and the photons begin? Or does
the antenna emit photons?

Agreed. But I needed a word to capture the similar concept
for frequency so I chose "normalize". Feel free to propose
another, and possibly less confusing, word.

I am not convinced. The value is still being determined
by accounting for all the other phase shifts and then
subtracting from 90. I would be more convinced of the
utility if the value could be computed from first principles
and then used, for example, to compute the length of
the whip.

Well I am not sure about the "true" nature of coils. When I look
at one of those coils, I think it is one big complicated mess of
distributed capacitance and inductance. There is intra and inter
turn capacitance and capacitance to ground. A mess.

Some say such a coil can be adequately modelled using a lumped
inductor. Corum thinks he can do better, but I doubt that even he
would claim that he has the "true" nature of such coils.

As an aside, allowing the possibility of this "phase shift" at the joint, how would you compute the phase shift when a parallel stub is used, or when multiple parallel stubs are used to obtain the desired result? And which stub will be used to define the 90 degrees from which the others are subtracted?

photons are a non-sequitar... or waves are, take your pick. but never the twain shall meet... except in some odd quantum mechanics cases where waves and photons are equally valid. For working with antennas at HF it is best to forget photons, they will just confuse you. if you get into the inner workings of lasers or BEC's or other quantum level effects then you might need to use photons. EM fields and waves in the macro world are all that is necessary to completely describe the solution to any problem you may encounter in amateur radio. likewise in transmission lines, forget photons, use currents and voltages, you will never run into a case where photons are

necessary, or even useful, in transmission line problems.

Just raise the stakes, Dan. Challenge Roy to prove the
impedance is -j567 without applying a source signal.

I wonder what is the ulterior motive in arbitrarily
handicapping the person doing the measurements?

Roy mentioned the TDR for the other problem. Seems a TDR
is exactly the instrument needed to find out what is in
each of those black boxes. Or just order the black boxes
already specified with its s22 parameter stamped on the
black box.

Yes, it illustrated the two separate and different
IEEE definitions for "impedance", one a cause for
the voltage to current ratio and one a result of a
voltage to current ratio.

>inductor.

I'm afraid you have fallen for someone else's mis-statement of that point of view.

The most recent posting about lumped inductance was probably mine. It states both the value and the limitations of this approach.

"Lumped inductance is often a good approximation to reality, so [most models other than Cecil's] very sensibly use that as their starting-point. Then they can progressively apply corrections for the distributed properties of a real-life inductors. The smaller those corrections are, the simpler the model becomes.

In practical terms, a lumped-inductance model will take you straight to a buildable prototype. The necessary corrections can then be applied by mechanical adjustment, without needing to model the distributed properties of the loading coil in detail. Such models are to be found in G4FGQ's MIDLOAD program, ON4UN's 'Antennas for Low Band DXing' and other handbooks.

There was also an excellent theoretical treatment by Boyer in 'Ham Radio', which shows in detail how the model of an antenna as an unterminated transmission line is COMPLETELY capable of incorporating lumped inductance."

You are still comparing apples and oranges.

Why not compare it to the 6000 joules dissipated each minute? Or the 360,000 joules dissipated each hour? Or the 8+ megajoules dissipated each day?

The length of time that we need to use for a fair comparison is the length of time it takes the forward energy to propagate from one end of the stub to the other. That time is about 62.63 ns for a 4 MHz 1/4WL stub, or 6.263E-8 seconds.

100 joules/sec times 6.263E-8 seconds is 6.263E-6 joules or 6.263 microjoules lost to radiation. That's 6.263 microjoules per 62.63 ns so the power remains the same.

The forward power is about 31 microjoules per 62.63 ns. The reflected power is about 25 microjoules per 62.63 ns.

The forward energy is about five time the radiated energy. The reflected energy is about four times the radiated energy. That's why the standing-wave current completely swamps the traveling-wave current such that it is extremely difficult to use that current for phase measurements.

Make the lossless stub one second long plus 1/4WL and then recalculate the energy stored in the stub.

The Smith Chart is NOT normalized to a frequency.
EZNEC outputs frequency sweep data that can be
imported into MicroSmith.

So by your own admission, those are not mechanical waves.
Like charge repulsion is *NOT a mechanical phenomenon*.
Those electrons never touch each other. They are repelled
by the photons they are emitting.

> I've been told that near the antenna, there are just

The varying field ***IS*** made up of *PHOTONS*.
All electromagnetic fields consist of photons!

Yes, all the boxes contain the same number of electrical
degrees. That's why we can calculate the number of
electrical degrees at the impedance discontinuity.

Hint: That number of electrical degrees for a capacitor
is the same as the gamma angle for the reflection
coefficient.

The ARRL reference included in the article is hardly a ringing endorsement and not addressed is the FCC's attempt to protect an unlicensed user from a licensed service.

You've ignored the reality of current BPL trials which *do* interfere with amateur radio. I provided a link to that story earlier.

> the whip.

That can easily be done. The s-parameter equations do
exactly that when applied at an impedance discontinuity.
a1, a2, b1, and b2 are all phasors each with an amplitude
and a phase.

b1 = s11*a1 + s12*a2

b2 = s21*a1 + s22*a2

The angle between b1 and b2 is the phase shift at
the impedance discontinuity.

Now are you convinced?

>> What happened to the missing 37 degrees?

> Perhaps, like the missing dollar, it is simply a number
> with no meaning.

Perhaps, if you would do the s-parameter analysis, you
would see the phase shift for yourself so it would
have meaning to you.

Fields and waves *are* quantized photons. Radiation
from an antenna is a lot easier to understand as
a cloud of photon particles that escape rather than
the EM fields that break away like soap bubbles.

"one useless man is disgrace 2 become a law firm 3 or more become a congress"
adams

woger you are a Congress all in your own head

http://kb9rqz.bravejournal.com/
altopia is never used by KB9RQZ
nor is Konstans@hotmail.com ever udsed on the usenet from anywhere but google and noow
motezrella

posts from these sorucees are fakes

and get ou the newly recovered KB9RQZ.blogspot.com as well

G

Cecil,

Only in your dreams. Antenna photons may be great for your handwaving explanations. Let's see you do the math. Do you suppose there is a conspiracy among the many authors of text books to use only the cumbersome wave formulations? Are photons too easy? Would the textbooks then be unneeded?

Do you really know that mother nature is not ALWAYS operating in small
steps of DC? How small is the scale that you can resolve to? I can not
answer where DC starts and stops. Maybe you can?
>
>> Is there some harm in considering Zo = 1/cC?

It seems that a simple yes or no answer could suffice here. How is
"privacy in the home" related to Zo = 1/cC?

Please elaborate about the "death grip on DC". How is DC related to
waves, or better, where does DC stop and waves begin? Should we never
consider any portion of a wave to be DC like we do in calculus routinely?

My original remark about about Zo = 1/cC expressed my surprise that such
a relationship existed. It was not an original discovery by me, only
new knowledge to me. From your reaction, this must be the first time
you have run across the equation and how it might be derived. I
provided two links to web pages where others have derived the equation
from a different aspect, and even more pathways exist. It seems to be a
very fundamental relationship despite being not well known or wide used.

OK, a completely new discussion that perhaps was not in your interest
to raise or expand upon here. I see nothing productive in it either.

>>> What is your point here? Are implying that the formula is incorrect
>>> because a sine wave was not mentioned in the derivation. I am sure that

>
>We agree on this.

So, are we to discard this phenomenon of the clumsy current bulge so
illustrated at one of your links? It seems to have injected this
aberrant usage of DC which then donned the mantle of Wave.

>>> We would complicate the concept and thereby begin to confuse people if
>>> we insisted on using the "Stepped Wave" term.
>>
>> They would've been confused anyway.
>

>They don't seem to be confused, once the limitations of human language

Then they are not confused, simple so stunned as to not ask the
questions you anticipate. I haven't seen any objections, other than
yours, to the term Stepped Wave. Are you referring to private
correspondence?

>>> It is a simple step to
>>> recognize that if we can make a wave front with one battery, we can use
>>> a lot of batteries and carefully place and switch them to form a sine
>>> wave. The more batteries and switches, the better the representation.

>answer where DC starts and stops. Maybe you can?

With great certainty and precision. I have measured the fundamental
units of DC out 7 places, traceable to the National Bureau of
Standards. I have also measured AC from sub-Hertz to 12GHz to the
highest precision and certainties in the same occupation. The body of
science and engineering is not confused about this demarcation.

For any purpose of discussion, DC is regarded by science and
engineering to mean either:
1. Static, non-changing potential (your discussion violates this);
2. Constant, unvarying current (your discussion also violates this).

If your current or voltage cannot subscribe to these commonly held
descriptions, your currents and voltages are not DC.

>>> Is there some harm in considering Zo = 1/cC?
>>
>> This is best left in the privacy of the home.
>
>It seems that a simple yes or no answer could suffice here. How is
>"privacy in the home" related to Zo = 1/cC?

I have stated the harm several times, repetition does not seem to be
adequate in that your having perceived benefit is a personal choice. I
see no reason to dwell on the subjective.

>Please elaborate about the "death grip on DC".

>How is DC related to
>waves, or better, where does DC stop and waves begin?

It was your premise. If you cannot explain it (and I see absolutely
nothing that would help you explain it) - then this is obviously the
end of the matter to which I first (see that question above) asked you

about.

>Should we never
>consider any portion of a wave to be DC like we do in calculus routinely?

Calculus is done "by parts." In derivation DC is the first thing to
disappear! In integration, DC arrives as an unknown! If this
discussion of Calculus were to progress any further, it would involve
dt which imagines no past, no future, just now. DC comes equipped
with all three nailed down to the same value.

>My original remark about about Zo = 1/cC expressed my surprise that such

It is no more fundamental than when Tennessee state law mandated that
the value of PI would be 22/7ths. Your fundamental is merely a
shortcut, not a fact of nature. Like that Tennessee law, you can't
use it for very much when push comes to shove. I certainly wouldn't
buy tires based on the circumference calculated from Tennessee law.

you should have gone with your gut and acknowledged the surprise by checking
your work and finding out why it doesn't exist... or why it is not used
instead of the real LC equations in all the text books.

> It was not an original discovery by me, only new knowledge to me.

Ok, if it was not your discovery, quote a reputable source where it was
discovered.
btw, your referenced web page 'speedingedge.com' has the formula correct:
Z0 = 1/(C v)
note, the v, not c in the equation. and CL should be C sub L.
also the uci.edu site has the formula exactly the same, with v instead of c.
so start searching again for one that has c in the equation instead of v.

Can not easily send you a picture, but it is pretty simple. It
merely snaps on the little RF connector on the tuning box.... between the
box and the edge of the coax plug. It swivels in various directions....
I have mine positioned to run back down alongside of the coax.... BTW,
as I understand it, that little 6" length only effects the tuning of
antenna for the 440 MHz band, and not 2M at all.

The formula will not give a "DC wave" velocity, but one can be found
from the experiment. First however, we must agree upon what unit we are
to assign a velocity to.

Perhaps this goes toward the definition of the unit of DC that we might
assign a velocity to?

Nope, just what I have seen on the news group.

My description of the experiment mentioned wave front several times. I
also assumed a steady current behind the wave front. Why are we
concentrating on the DC part to the exclusion of the wave front?

BTW, congratulations on measuring characteristics out to several decimal
places. That takes great care, precision, and skill.

This again goes to defining the unit of DC that we wish to assign a
velocity to.

Am I to understand that the only use of the term "DC" that you will
accept is "A steady state without beginning or end, having always
existed, and will exist forever more". Of course such a thing would not
have a "wave front"

A shortcut assuredly. Also another view of the physical world. Use it
when helps understanding, and abandon it when the model fails. After

all, no matter what precision we measure to, we are just working with models. Perhaps the next decimal of precision will reveal a flaw or hole in logic.

> starting-point.

For the umpteenth time, Ian, I don't have a model developed
by me. The model I use is the distributed network model
invented before I was born. Dr. Corum merely expanded upon
that model and I consider his concepts to be valid.

Your lumped circuit model seems more like a religion
than a valid tool of science. Zero phase shift through
a real-world loading coil? That requires faster than
light propagation thought by many experts to be
impossible.

Good grief, that goes against The Bible which says the
value of PI is 3.0 and "everyone knows" The Bible cannot
be wrong because God inspired it to be written that way.

Moral: Change the frequency and then observe what one
is dealing with?

> I suggest that there is no value in thinking about
> the "phase shift" at the discontinuity (which depending
> on the black box chosen might not be present), and
> merely think about the results of connecting the
> -j567 impedance to the 600 ohm line.

The refusal to think about the phase shift at the
discontinuity is what got this whole thread started.

All you have to do to observe the calculated phase
shift is to use the s-parameter equations. When you
have done that, please get back to us.

> Cecil did not answer the question, so I will
> pose it again. If knowing the phase shift at

> would you refuse to calculate the length
> of 600 ohm line needed to produce 0 ohms?

Or asking the question another way: Is there
really a Santa Claus and a God?

Let's see you prove that it is really -j567 ohms
without applying any signal at all. How's that
for a requirement?

Sometimes an epiphany takes place in an associated
area. I was searching for the loaded whip answer
when I stumbled upon the dual-Z0 stubs, a subject
that seems to have been ignored in the amateur
literature.

Sorry, I had a migraine and a brain fart there.
The angle between b1 and a2 is the phase shift
at the impedance discontinuity. It's absolute
value should be the same as the angle between
a1 and b2 at the impedance discontinuity.

I apologize for my brain fart.

I vote for 3.2 and so did the Indiana legislature by 67 - 0!

From:
http://www.agecon.purdue.edu/crd/Localgov/Second%20Level%20pages/Indiana_Pi_Story.htm

The Indiana Pi Bill, 1897

This is Indiana House Bill No. 246, 1897, known as the Indiana pi bill.
Towards the end of section 2 it says plainly that "The ratio of the diameter
and circumference is as five-fourths to four," which means pi is 3.2. The
section goes on the criticize (ungenerously, I'd say) past values of pi as
"wholly wanting and misleading."

ENGROSSED HOUSE BILL No. 246

A Bill for an act introducing a new mathematical truth and offered as a
contribution to education to be used only by the State of Indiana free of
cost by paying any royalties whatever on the same, provided it is accepted
and adopted by the official action of the Legislature of 1897.

Section 1
Be it enacted by the General Assembly of the State of Indiana: It has been
found that a circular area is to the square on a line equal to the quadrant
of the circumference, as the area of an equilateral rectangle is to the
square on one side. The diameter employed as the linear unit according to
the present rule in computing the circle's area is entirely wrong, as it
represents the circle's area one and one-fifth times the area of a square
whose perimeter is equal to the circumference of the circle. This is because
one fifth of the diameter fails to be represented four times in the circle's
circumference. For example: if we multiply the perimeter of a square by
one-fourth of any line one-fifth greater than one side, we can in like
manner make the square's area to appear one-fifth greater than the fact, as
is done by taking the diameter for the linear unit instead of the quadrant
of the circle's circumference.

Section 2
It is impossible to compute the area of a circle on the diameter as the linear unit without trespassing upon the area outside of the circle to the extent of including one-fifth more area than is contained within the circle's circumference, because the square on the diameter produces the side of a square which equals nine when the arc of ninety degrees equals eight. By taking the quadrant of the circle's circumference for the linear unit, we fulfill the requirements of both quadrature and rectification of the circle's circumference. Furthermore, it has revealed the ratio of the chord and arc of ninety degrees, which is as seven to eight, and also the ratio of the diagonal and one side of a square which is as ten to seven, disclosing the fourth important fact, that the ratio of the diameter and circumference is as five-fourths to four; and because of these facts and the further fact that the rule in present use fails to work both ways mathematically, it should be discarded as wholly wanting and misleading in its practical applications.

Section 3
In further proof of the value of the author's proposed contribution to education and offered as a gift to the State of Indiana, is the fact of his solutions of the trisection of the angle, duplication of the cube and quadrature of the circle having been already accepted as contributions to science by the American Mathematical Monthly, the leading exponent of mathematical thought in this country. And be it remembered that these noted problems had been long since given up by scientific bodies as insolvable mysteries and above man's ability to comprehend.

LEGISLATIVE HISTORY

Introduced
IN THE HOUSE
Read first time January 18th, 1897
Referred to Committee on Canals
Reported and referred to Committee on Education January 19th, 1897
Reported back February 2nd, 1897
Read second time February 5th, 1897
Ordered engrossed February 5th, 1897
Read third time February 5th, 1897
Passed February 5th, 1897
Ayes - 67 - Noes -0-

Introduced by Record
IN THE SENATE
Read first time and referred to
committee on Temperance, February 11th, 1897
Reported favorable February 12th, 1897
Read second time and indefinitely postponed February 12, 1897

Hi Roger,

Exactly. This has always been the definition for DC. For anything
else, there are already terms that have been provided for decades,
unto more than a century.

> the storm of 100s of millions of internet users ...

Knock off the BPL cheerleading, "John". We radio amateurs are licensed. Licensed services are supposed to be protected from unlicensed radio spectrum users. Now there are radio users who deserve to be protected from BPL as well. Anyone who owns a shortwave receiver and wishes to listen to a signal in a frequency range not notched by a BPL provider is out of luck. It shouldn't be that way. Pollution is pollution.

> There is reality and "Heil Dreams."

I'm not dreaming any of the thoughts I've written. They are reality. Nothing I've outlined is untrue. You, on the other hand, are an anonymous fellow posting irrelevant material to an antenna newsgroup. You must be a Fig Newton of my imagination.

Dave K8MN

Why would anyone refuse to calculate the length of
600 ohm line needed to produce 0 ohms? I think I
was the first to calculate it at 43.4 degrees.

That last line makes it "your model" by adoption - and certainly "your model" by advocacy.

>Your lumped circuit model seems more like a religion
>than a valid tool of science. Zero phase shift through
>a real-world loading coil?

That wasn't what I said. What I did say - and you cut - was:

"Lumped inductance is often a good approximation to reality, so [most models other than Cecil's] very sensibly use that as their starting-point. Then they can progressively apply corrections for the distributed properties of a real-life inductors. The smaller those corrections are, the simpler the model becomes.

In practical terms, a lumped-inductance model will take you straight to a buildable prototype."

MI5 Persecution: How Could It Be True?

If you have the patience to read these articles you will be struck by how apparently fantastic the claims being put forward are. You may ask yourself why such seemingly nonsensical assertions are made. This matter has been discussed on the Internets UK-local newsgroups for three years now, and the denizens of the uk.misc newsgroup (the so-called "miscreants") have come up with a number of theories to explain these posts; it has been variously suggested that they are a troll (an artificial creation for the amusement of its author), that they are made by MI5 themselves with the purpose of discrediting other conspiracy theories, and that the poster is mentally ill and the articles are symptomatic of the illness (the view held by most miscreants).

Are these claims the product of mental illness, or is that just a cover?

The most obvious explanation, that the claims made result from the admitted mental illness of the author, is the one which the persecutors intend be the one accepted without consideration being given to the possibility of the claims being true. The persecutors have actually been very clever about this, both in selecting as their target someone who was known from school or university as being borderline schizophrenic, and in ensuring the nature of their persecution corresponds to what often features in the delusions of a schizophrenic.

The very first incident of the persecution occurred in June 1990, when I was still a student at university in London. It consisted of a reaction (giggling) from the newsreader, Sue Carpenter of ITN, to what she saw happening in my living-room at my parents home where I was living. Before your imagination gets the better of you I should make clear that what the newsreader was reacting to was not too embarrassing in nature; my mother had brought an apple for me into the the room, and Sue Carpenter found this amusing.

I recognized that Carpenter had reacted to what she had seen in my living-room, yet this idea still seemed completely fantastic to me. My reaction was to continue watching television, particularly the news, to see if this incident would be repeated. It was, many times, both on BBC and ITV. An intelligent person would have thought to obtain a video recorder and capture some of these incidents in order to try to explain to an observer what he saw in these broadcasts. Unfortunately, I failed this test of intelligence, since I did not record these programmes. I have recently attempted to obtain from ITN tapes of their news programmes dating back to summer 1990, but, unhappily, they have advised me that they

do not have complete programmes including newsreaders comments dating back to that period.

From the outset, the persecutors structured their actions to ensure that any complaint would be met with disbelief, and dismissed as delusional. This is why they chose as their target someone who was known at school and university to be borderline mentally ill; and it is why they fired the first shots of their campaign through the broadcast media. Schizophrenics commonly believe the media harass them; it would be exceptional for "full-duplex television" to exist in reality. Those with schizophrenia also commonly believe people are talking about them; again, the persecutors have shown themselves very rarely, but act through intermediaries, both in the workplace, and in public and during travel.

Mental illness is not the cause of these claims, but the simulation of its symptoms is a cover used by the persecutors to deny their victim the ability to have his compaints believed.

What evidence exists to support these claims of "interactive television/radio";?

Quite frankly, I have very little evidence to support my claims. You may examine the "Evidence" area of my website to see such evidence as I have been able to gather. None of it is remotely conclusive. The "smoking guns" all date back to 1990/91, and it is really rather late now to start trying to look for material dating back seven or eight years. In 1997 I started tape-recording every programme I watched or listened to. I also started carrying with me a high-fidelity minidisc-recorder with good quality microphone to catch incidents of public harassment, but this also has not been as successful or conclusive as I had hoped.

Perhaps the best item in the "Evidence" section is the audio file "Life is so hard" (it is labelled with Garfield the cartoon character on the site), which I have given a certainty level of 100%. This item relates to harassment at my workplace in Canada in 1996. A co-worker called Mark was coming up with phrases and expressions which were repeating things being said at my Canadian residence, consequently leading me to believe that my apartment and home phone were bugged, and that the persecutors were passing their gathered information on to Mark. On one particular evening I said in my apartment, "life is so hard, and then you die". The following day I was able to record Mark saying exactly the same phrase at work.

Unfortunately when "they" know you are recording them, they simply dont say things which would unambiguously show harassment. When Mark the co-worker knew he was being recorded, he only made his remarks out of range of the recorder, for example outside the building. When the TV newscasters or radio disc jockeys know they are being taped, they limit themselves to saying things which are ambiguous, which even in my mind may or may not be personally directed against me.

Who knows about this persecution?

Surprisingly many people know. People in the media, such as BBC and ITN newscasters including Martyn Lewis and Michael Buerk, and radio disc jockeys such as Chris Tarrant of Capital Radio, know what is going on, and take part in it. Some co-workers at my former workplaces in England and Canada have known about the harassment. Quite a few people in the general public are also included. I believe the police are aware of the persecution, but, unfortunately, have chosen not to take any action to stop it. I have complained at my local police station in London several years ago, and I have stated on the internet newsgroups that I have done so, hence the police will be well aware of my wish to see the matter resolved. I believe their inaction denotes a dereliction of duty, but without good evidence, I am powerless to compel them to take steps to prevent further harassment, or deal with what has already taken place.

What is the purpose of sending these faxes?

These faxes are being sent to three distinct groups of people, namely Members of Parliament, the media, and diplomats & legal people. As you will have observed I am making use of the email-to-fax gateway at Demon Internet to send these faxes. I am forced to use this gateway since I currently live in North America, and cannot afford the high cost of direct phone calls to the UK.

My purpose in publicising my claims is firstly to discourage the persecutors from continuing their campaign, and also to attempt to bring their campaign out into the open, and thus perhaps identify the persecutors. Neither aim has been achieved yet, but I hope that with sufficient stimulation these aims may yet be accomplished.

The problem with the second aim is that those who read this article will fall into two groups, those who dont know anything about the persecution and consequently will disbelieve my claims as delusional, and those who do know about the harassment and may have some idea of who is behind it, but realise that if the harassers are exposed and the truth brought out into the open, then powerful British institutions will substantially lose prestige, and be exposed to ridicule.

It would give me hope to believe that these faxes will create a third group of people, those who find out that I am telling the truth, and who follow their consciences in standing up and seeing justice done. Only time will tell if this hope will be realized.

Exactly. Why would anyone refuse?

So the next question is: What is the phase change
at the terminals of the black box?

1) -93 degrees? (previous answer when it was a capacitor)
2) 36.6 degrees? (previous answer when it was 10 degrees of 100 ohm
line)
3) 0 degrees? (previous answer when it was 46.6 degrees of 600 ohm
line)
4) undecidable?
5) undefined?
6) irrelevant?
7) ???

3470. MI5-Persecution: Why do you think MI5 are responsible? (3112)

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-16 11:50:37 UTC
From: MI5-Victim@mi5.gov.uk

Why do you think MI5 are responsible?

The question of who is ultimately responsible for this eight-year harassment is one which is very difficult to answer, as the persecutors have never clearly made their identities known to the persecutee. However, I believe I am correct in attributing the continuing victimisation to elements of the British Security Service MI5, and in this article, I will try to explain the reasons for this belief.

The British internet magazine ".net" featured my website on page 17 of their March 1998 issue (number 42). Their review kindly describes it as an "excellent site" and gives some details of what the net surfer will find there. Should you wish to reply to this article you can do so;

"When did you first suspect MI5 were responsible?"

Over Easter 1995 I went to see a local solicitor in London with a view to talking to the police about the harassment. Soon afterwards I did go to my local police station in Clapham and spoke to an officer there. The solicitor made a comment which suggested to me that the persecution I had been experiencing may have been organised by an intelligence service.

Up to this point, I did not have any clear idea as to who was behind the harassment. Only their agents were visible, in the media, on television news programmes, and on the radio; in the workplace, where things said at my home were repeated verbatim; and in some cases abuse in public and during travel, for example on the trip to Poland in June 1992 which I have already described.

Both from the fact that widely disparate individuals and organisations were employed as agents in the campaign against me, and from the fact that an entity would be required to marshal their resources in the areas of spying on my home and giving gathered information to their agents, it was clear to me that a single entity was responsible for carrying out the campaign. Yet from June 1990 until Easter 1995 I did not have a clear idea of who might be responsible. I guessed that perhaps some private individual or group of persons who saw themselves as my enemies had perhaps paid private detectives to organise the harassment. Alternatively, since the campaign had started in the media, I made a far-fetched supposition that perhaps it was an ad-hoc group of media people who had set themselves up in opposition to me. After Easter 1995 I saw that these guesses were wrong, and I made an I believe much more accurate estimate as to who my enemies really are.

"Why couldn't a private group be behind the persecution?"

There are several reasons why a private individual or group would not be behind this campaign.

Quantity of resources / Money. Here is what one Usenet (internet newsgroup) participant had to say (several years ago) on the topic of how much money it would cost just to keep the surveillance going.

PM: >But why? And why you? Do you realize how much it would cost to keep
PM: >one person under continuous surveillance for five years? Think about
PM: >all the man/hours. Say they _just_ allocated a two man team and a
PM: >supervisor. OK., Supervisor's salary, say, #30,000 a year. Two men,
PM: >#20,000 a year each. But they'd need to work in shifts -- so it would
PM: >be six men at #20,000 (which with on-costs would work out at more
like
PM: >#30,000 to the employer.)
PM: >
PM: >So, we're talking #30,000 x 6. #180,000. plus say, #40,000 for the
PM: >supervisor. #220,000. Then you've got the hardware involved. And
PM: >any transcription that needs doing. You don't think the 'Big Boss'
PM: >would listen to hours and hours of tapes, do you.
PM: >
PM: >So, all in all, you couldn't actually do the job for much less than
PM: >a quarter million a year. Over five years. What are you doing that
makes
PM: >it worth the while of the state to spend over one and a quarter
million
PM: >on you?

A private individual or group would not spend over a million pounds to verbally torture a victim without some financial motive or gain. Private industry is driven by the profit motive, and there is no financial profit to be had from carrying out a campaign in this way. If a private enterprise were behind it then they would have taken direct physical action a long time ago.

State enterprises, on the other hand, can afford to be wasteful, since they are funded by the taxpayer. They do not have to show a money profit. The employees or contractors employed by a state organisation such as MI5 are driven by their own personal profit motives, to make the most money out of their employers for the longest period of time. MI5 is funded to the tune of #150M p.a.; even a few hundred thousand a year would to them be affordable if their managers could convince themselves of the necessity of what they were doing.

Quality of resources / Technical resources - electronic and other surveillance. In summer 1994 a reputable and competent private detective agency was employed to conduct a counter-surveillance sweep of my home in London. They charged us over #400 for this, conducted a thorough search for radio transmitting devices, hard-wired "probe" microphones and also tested the telephone line. They found nothing. This was not altogether surprising, since it had been made very clear to me that there were bugs

in my home; the "buggers" would not have made this clear unless they had felt their bugs were of sufficient sophistication as to be safe from detection.

But there is another lesson to be gained from the failure of the private detectives to find anything. The agency employed was one of the most reputable in London. They were employed on the principle of "setting a thief to catch a thief", for if the harassment were being carried out by private detectives, as I then believed, then surely another set of private detectives would be able to find the bugs that they had planted. That these "private eyes" were unable to find anything, and that the harassers were confident that they would not be able to find any bugs, points to the harassers being an order of sophistication above a private agency, and leads me again to believe that a state intelligence service is responsible for the surveillance and harassment.

Quality of resources / Technical resources - Interception of Postal service. In summer 1994 when I emigrated to Canada to try to escape the harassment, I wrote letters home to my family and friends in London. Quite soon after my arrival in Canada, the harassers were able to find precisely where I was staying. The only way I can see of "their" being able to find out my new address was by interception of my letters to the UK.

Later in 1994, I conducted an experiment to see if my letters home were indeed being read. In a letter home I wrote of being depressed and talked in vague terms of suicide. I deliberately chose this topic, since I believed it was the outcome my harassers were trying to achieve, and that if they read the letter, they would "echo" its contents. Sure enough, soon afterwards there were two incidents of people shouting "suicide" at me in public places in Canada.

It is inconceivable for a private agency to have the ability to intercept postal mail. The state security service on the other hand is well known to engage in these activities.

Quality of resources / Access to Media. One of the strangest aspects of this case is the access "they" have to the broadcast and print media. I still do not understand what could persuade newscasters such as Martyn Lewis and Michael Buerk, who consider themselves "gentlemen", to behave in an almost voyeuristic way by "peeking" into the living room of one of their viewers. A year ago I wrote to the BBC asking if these newscasters would confirm or deny the accusations made against them. The BBC replied that their newscasters had denied the accusations, but refused to do so in writing.

It is well known that MI5 have the ability to plant stories in certain newspapers, but convincing television newscasters to "watch" a viewer while they read the news would surely be very difficult for them to accomplish, unless they presented themselves to these journalists as being, for example, a group in the media who were seeing to it that I got my "deserved" treatment. MI5 has a history of manipulating the media, so it might not be too difficult for them to accomplish such a trick, whereas

a private group would not have this ability.

"Have they ever denied that they are the Security Service?"

No. Never. This is in fact the main reason why I believe "they" are MI5 and not a privately funded group. If my guess had been wrong then I am sure that "they" would have crowed over my mistake, but they have never admitted nor denied that they are employees of MI5.

In early January 1996 I flew on a British Airways jet from London to Montreal; also present on the plane, about three or four rows behind me, were two young men, one of them fat and voluble, the other silent. It was quite clear that these two had been planted on the aircraft to "wind me up". The fat youth described the town in Poland where I had spent Christmas, and made some unpleasant personal slurs against me. Most interestingly, he said the words, "he doesnt know who we are".

Now I find this particular form of words very interesting, because while it is not a clear admission, it is only a half-hearted attempt at denial of my guess that "they" = "MI5". Had my guess been wrong, the fat youth would surely have said so more clearly.

"If MI5 were behind it, why would they wish to mask their involvement?"

I have heard a number of times a belief from people in the media that it is they, the media people, who are behind the abuse. In spring 1994 Chris Tarrant the Capital Radio D.J. said sarcastically on his breakfast show, "You know this bloke? he says were trying to kill him. We should be done for attempted manslaughter". We, we, we. Tarrant thought it was a media conspiracy.

Returning to the question of "interactive watching" by television newscasters, it would again be much easier for them to take part in that sort of activity if they convinced themselves that the surveillance and abuse were organised by "their own", by media people. It must be second nature to MI5 to mask their involvement in the matters they deal with; in this case, they pretend the campaign is organised by a group in the media, and any journalists who suspect otherwise keep their silence.

Conclusion

Over the last three years I have stated with some force my belief that MI5 are responsible for my misfortunes. I have done so on Internet newsgroups, in letters and faxes to people in politics and the media in the UK, and in 1997 I made a formal complaint to MI5 regarding their activities; the Security Service Tribunal replied in June 1997 that "no determination in your favour has been made on your complaint". (I believe the statement by the Security Service Tribunal can be disregarded, as they have never, ever made a ruling in favour of a complainant.) In three years of naming MI5 as my oppressor "they" have never denied the charge. To me, their silence on this point indicates that my guess was accurate. I believe my persecutors stand identified. The question of why they should carry out this campaign is one I will try to answer in a future article.

MI5 Persecution Update: Friday 15 May, 1998

The persecution has been quite severe for the last week. It appears that my enemies are reacting to the steady stream of faxes making their way over the Atlantic to the fax machines of Westminster politicians and the media. Here is whats happened in the last few days;

The week started off with an incident in the cafeteria at a local shopping centre where I habitually drink my morning coffee. My enemies have concentrated since winter 1995/96 on throwing a particularly horrible sexual slander against me. They "put people up" to repeat this slander against me, and this is what happened again here.

On Thursday morning (yesterday), instead of going to the usual cafeteria I went to a nearby convenience store for coffee. The same horrible sexual slander was shouted at me very loudly by a member of staff as I walked into the store. This was the first time I had ever bought morning coffee in that shop. The other staff obviously knew what was going on, one of them said, "they screwed up my life".

The fax gateway I use to send these faxes to the UK has been working hard these last few days to shut down my access by barring the accounts I use to send these faxes.

I have received an anonymous threat from fax number 0171-219-6101 (the machine gave its name as "ETRA-HoC") which said, "Stop sending to this fax no 0171-219-6101 or else" (the consequences of continued transmission were unspecified). I invited the sender to apologise for his threat, but received no response.

This all adds up to quite a severe reaction to my faxes of the last few weeks. I actually find this quite heartening since it shows that my faxes are finding the mark and there may yet be a breakthrough in my efforts to expose the Security Service conpiracy of abuse against me which has now been going on for eight years.

MI5 Persecution: "Why would they be doing this to you, sir?"

This article will concentrate on the difficult question of "Why". The question which forms the title of this piece was asked of me by the police officer I spoke to in Easter 1995, when I went to make my complaint.

There are really two sides to this question. Firstly, why should MI5 be harassing anybody in this fashion? Secondly, if they choose to behave in this way, why should they have selected me in particular, and not somebody

else? Alternatively, why did the persecution start, and why is it continuing?

I do not have definite answers to either side of this question, since my persecutors have usually kept themselves hidden and only acted through other parties. To know "why", one would have to know who the persecutors are, and something of their personalities, since their abuse is almost certainly symptomatic of a personality disorder of the abusers. Certain things however can be deduced about the abusers from the nature of their behaviour, and I will talk about this later in the article.

Why did it start?

It is clear that the persecution must have been initiated by someone who knew me personally, either at school, or at university, or socially, and knew that I was borderline mentally ill, since this is what makes me a target for the persecutors. Unfortunately, the originators have never been identified, and there are several possible candidates. Neither has the link from the originators of the persecution, to the persecutors themselves, ever been made clear. So who are the originators?

University Staff

The identity of the originators may lie in the timing of the persecution. It started in June 1990, while I was finishing a course at Imperial College in London, and a year after I graduated from Cambridge, where I received a degree in computer science. At Cambridge I had achieved some notoriety in the computer lab from various nefarious exploits. Roger Needham attacked me by saying that "there were great hopes for it, but it failed terribly". When I started at Imperial I found that my reputation had preceded me; Cambridge computer lab had spoken to I.C. lecturers about me. I.C. lecturer Frank McCabe summed up commenting about "setting up a straw man so you can tear him down". (Despite being "torn down" by the Cambridge computer labs lecturers, I still achieved a good first degree and a Masters degree at Imperial.)

Other students at university

So, the originators may have been university staff who knew me from my student days. But there are other possibilities. I had other enemies at university, including some fellow students. At my Cambridge college it was common knowledge that my mental health was dubious, and it was known that I talked to myself in my sleep - the floor and walls were quite permeable to noise, so other students heard. I was given the nickname "gibber" because of this habit. Sometime later, I managed to catch myself talking in my sleep when I woke up in the middle of the night.

Here is a quote from a participant in the internet newsgroup where I have been posting for the last three years;

>One thing which has been missing from this discussion is this simple
>prognosis: that maybe he is right and that, despite his admitted
>mental condition, there really is a campaign against him organised by

>now-influential ex-students of his university.

People I knew socially

I had yet other enemies in 1990 (I am a man of many enemies!). In January 1990 I broke up with some people I had been going out with socially. One of them, by the name of Andy Turner, wrote a letter to Alan Freeman, who at the time was a Radio 1 DJ. Freeman read part of the letter out on his Rock Show, about the "one who wore out his welcome with random precision", saying "thats a hell of a letter you wrote there Andy", and "with a schizophrenic youre never alone".

It is my belief that Andy Turner and his friends were trying to make trouble for me, and Turner wrote to Freeman with this in mind. Freeman may have discussed the letter with others, and things may have snowballed from there. This is, of course, pure supposition. The fact is that I do not know who the originators are, and can only guess.

Once it started, why is it continuing?

The answer to this question is obvious. It is unacceptable to the "powers that be" in the UK to have somebody running around who knows he has been targeted by the Security Service and media organizations, and who is in a position to embarrass British institutions. This has become particularly evident in the last week; as I send more faxes to UK politicians and media, so the pressure on me grows, and the volume of abuse increases.

Part of the reason the persecution continues is in the personalities of the abusers, and it is this subject to which I will turn to next, since the key to understanding the persecution lies in understanding those who carry it out, as much as we can.

The Security Service operatives, the persecutors, are they psychopaths?

Let us first examine the definition of the term "psychopath". DSM-IV defines "anti-social personality disorder" as a "pattern of disregard for and violation of the rights of others ... deceitfulness, irritability and aggressiveness ... consistent irresponsibility and lack of remorse". The Harvard Mental Health Letter of Sept 1995 describes these people as using "charm, manipulation, intimidation and violence to control others and satisfy their own needs. Lacking in conscience and in feelings for others, they cold-bloodedly take what they want and do as they please", having "no guilt or regret".

I must say, reading this description of the condition, that it fits the persecutors perfectly. The persecutors have never shown the slightest remorse or guilt. Even when I was severely ill, they continued to abuse me. They have repeatedly blamed their actions on me, which is another trait common amongst psychopaths. They have no respect for my legal or personal rights, and they use intimidation and verbal violence.

If the MI5 operatives are psychopaths then it would explain both why the persecution started, and the degree of verbal violence. Psychopaths by

definition damage other people; here, the MI5 operatives find an outlet for their personality disorder, through "cripple-kicking".

Xenophobia on the basis of mental illness, and race

My enemies have made clear many times that one of the reasons they are persecuting me is because of my admitted mental illness. However, it is my belief that they are also persecuting me because I am not of ethnic English origin, and the fact that there have been several incidents of an overtly racist nature reinforces this view.

In one case, two youths on a tube train in London made openly racist references to me as a "soft toy, not up to British Standards". Another person near my home made remarks about "Polish people". In yet another incident in Croydon, a youth made comments about "foreigners".

But the main thrust of their xenophobia is because of my mental illness. I should make clear that I do not look ill; if you met me, you would not know that I had the illness. I take a relatively low dose of medication, and feel quite well. But the persecutors have repeatedly harped on about my supposed serious mental illness; they have called me a "nutter", a "schizophrenic", etc. They have also persuaded other people to use these terms of abuse. They are able to get away with this because abusing the mentally ill is still something which is mostly acceptable in Britain; the media do it, "nutter" is not taboo in the way that "nigger" is.

Conclusion

There are several groups of people who might have wished to cause me trouble, and I still do not know who originated the persecution. Nor do I know how the originators came to be in contact with the (presumed) Security Service operatives who have been carrying out the campaign. To know conclusively why it started, we would have to know who started it, and this information is not available.

However, we can infer some things about the personalities of the persecutors from their methods, and from the degree of verbal violence they employ. It is clear that a main reason for the continuing harassment is the psychopathic disorder of the MI5 agents who carry it out. That they have never been "brought to book" for their misdeeds reinforces their belief that they do no wrong; and, unhappily, until they are brought to book, their persecution campaign looks set to continue.

MI5 Persecution: .net Magazine Applauds my Website

The March 1998 issue (number 42) of .net Magazine reviews the MI5
Persecution website describing it as an "excellent site". The webpages
describe in detail the nature of my persecution since 1990 by what are
believed to be elements of the UK security service.

(snip image)

You are encouraged to read the web pages which include

o a FAQ section outlining the nature of the persecutors, their methods
of harassment through the media, people at work and among the general public
o an evidence section, which carries audio and video clips of media and
workplace harassment, rated according to how directly I think they refer to me
o factual descriptions of the state security agencies involved
o scanned texts of the complaints I have made to media and state security agencies involved
o posts which have been made to netnews over the last three years on this topic

MI5 Persecution Update: Friday 13 November, 1998

If You Intend To Reply, Please Read This

If you have any questions or observations you would like to share with me, then you are very welcome to reply to my fax number 0171-681-1190. But please.... keep your response to one page if you can! I have had several people faxing my article back to me, including one MP faxing back twenty pages. I do not know if he had anything intelligent to say in his 20-page fax because I applied judicious use of the "Delete" key on my computer. Faxes over a page or two will be deleted without being read.

MI5 Resume Hostilities in Response to these Faxes

When I wrote last weeks "MI5 Persecution Update" I remarked how quiet my life had become. No longer! MI5 have restarted hostilities with a vengeance the past week, in response I believe to the faxes I have been sending to members of the House of Commons.

On Saturday 7 November I went to Clapham Picture House cinema to see the film "Antz" (a very enjoyable film). At the cinema, I was verbally assaulted by a group of teenagers with the words "still crazy", repeated about ten times. There was a film with that name showing at the cinema, but it was clear their abuse was directed at me. I do not look ill, so why would they pick on me? answer, the incident was set-up by the persecutors. One of the teenagers also said to another, "I don't know what we're laughing at".

The following day, Sunday 8/11/98, I was on my way to play squash when I was verbally assaulted by a youth who said "it was so funny", without the slightest trace of humour. What he meant by this phrase was that was funny, and they were trying to humiliate me. I have heard this phrase "it was so funny" used at me before many, many times over the last eight and half years.

Please Encourage Keith Hill MP to Help Me

I live in a bugged house, bugged both for audio and video. My movements are monitored by MI5. The Security Service have followed me to Canada, to Poland and the Continent, to the States. I cannot work anywhere, not in England, not in Canada, because MI5 will destroy whatever employment I am able to obtain. I have asked Keith Hill MP to help me, and he has refused.

The situation is intolerable. It is Mr Hills job to help me out of this mess. So, please, as I said in the last fax a week ago: Do not waste your

time returning multiple copies of my faxes to my fax mailbox, as some of you have done. Instead;

Please encourage Keith Hill M.P. to help me.

I am sorry to be using this device to encourage Mr Hill to help, but I think eight and half years are quite enough and it is time something was done to bring this matter to a close.

MI5 Persecution : BBC Newscasters Spying on my Home

This week's topic is the quite extraordinary claim that BBC newscasters such as Martyn Lewis and Michael Buerk have spied on my living room while they read the news. I currently have an advert running for the next six months in Private Eye's "Eye Say" column (at a cost of over ₰200) which says,"MI5 Persecution - BBC Newscasters Spying on my Home"; the story of my campaign in the Eye is on my Website at; http://www.pair.com/spook/evidence/plaint/priveye.htm

BBCs staff magazine Ariel also ran my advert "BBC Newsreaders Spying on my home" for one issue in the Personal category on 8/July/1997 before it was spotted and axed by editor Robin Reynolds; please see webpage; http://www.pair.com/spook/evidence/plaint/ariel.htm

Beginnings

The very first incident in the "MI5/BBC Persecution" occurred in June of 1990, when a newsreader reacted to what she saw in my living room at home as she read the news. My mother had brought an apple for me into the room, whereupon the newsreader smirked and giggled, apparently finding this funny. I couldn't believe what I was seeing. I carried on watching news and other television programmes to see if presenters would show signs of "interactive watching"; to my surprise, this happened again and again. Unfortunately, I did not have my wits sufficiently about me to videotape these programmes, and it is now almost impossible to obtain recordings dating back to 1990.

Most of the "TV watching" has occurred on the news, and most of it in summer 1990, although some as late as autumn 1993. My website has a few extracts of what might be politicians "getting at" me, in particular John Major and interviewer Dimbleby sharing a joke about the "Knutsford Guardian" which is almost certainly about me.

I sold my portable TV in autumn 1990 and stopped watching television regularly. I realise now that this may have been a mistake. What I should have done was to watch TV and listen to the radio, but tape-record everything and make a note of what each excerpt meant to me. I would then be in a much stronger position as regards to evidence that I am now. That is what I am trying to do now, but unsurprisingly the TV/radio presenters have stopped getting at me, now they know they are being recorded.

Examples of Media Harassment

Here are a few examples which I can still remember of media harassment;

In early 1992 I was watching the BBC news with Martyn Lewis on a small black-and-white portable television at my then home in Oxford. I threw a term of abuse at Lewis; he flinched, then gave a grin and made a comment from which I understood that he had been on my side, but might have changed his mind as a result of what Id just said to him.

Victor Lewis Smith in his TV (BBC2?) program at the end of 1993, had a taxi-driver saying, "theyre all out to get me", to which VLS replied, "but you're quite intelligent aren't you?" (what a nice chap VLS is, compliments no less!)

Paul Daniels the TV magician, sometime in 1990-92 (sorry I can't be more precise but it was so long ago), made a "crying face" and put his face in his hands, which was his way of expressing that I was frequently crying in 1990-92, and that he and other media people found my crying funny.

Kenny Everett (deceased) on some talk show, compared me to a "huge ape" who "scratches himself"; he made some other remarks about what the "ape" got up to which unfortunately I cant remember. (I remember that Everetts comments were quite sympathetic and human, but were obviously about me.)

Stephen Fry on another talkshow (Wogan I think) talking about "masturbatory fantasies", he then referred to me with the words "you prat"; I wonder if the studio audience knew what he was talking about and to whom his comments were directed?

Griff Rhys Jones on Clive James' TV show, made a "lunatic face" (wide fixed grin) to which I said to the TV that he had a "face like a horse's arse", to which Clive James said to GRJ "did you hear that?"

Crimestoppers summer 1990, remarks by a Midlands police officer on the programme, while Nick Ross was presenter (as far as I can remember). The officer talked about "in car entertainment". Nick Ross said to officer, "why don't you stop doing it?" to which he replied, "we can't while he's like this".

BBC2 Newsnight in autumn 1993 had a piece on football hooliganism. A black interviewee said apparently of the hooligans, but in fact of me; "they're just idiots, carry on with the surveillance".

There was an incident with Jonathan Ross which I remember clearly; he was on both BBC and ITV television at the same time, one (ITV I think) was recorded, the other channel was live. Ross has a speech impediment which causes him to pronounce his "r"s as "w". I sarcastically said something about "Mr Woss" to the recorded channel, then turned over to where he was live, and he repeated "Woss" with heavy emphasis and sarcasm.

On the radio, in spring 1994, Chris Tarrant made a sarcastic remark in his morning show, saying "he says were trying to kill him, we should be done for attempted manslaughter", to which another of the studio staff said, "oh no, dont say that". His comment was in reply to a comparison Id made the previous evening between my persecutors and the Polish secret police who murdered dissidents.

Martyn Lewis Denies & Lies, But Wont in Writing

In February 1997 I wrote to BBC Viewer & Listener Correspondence and asked them to investigate the claim that their newscasters had engaged in "interactive watching". They replied that they had asked Martyn Lewis and Michael Buerk whether they had engaged in such practices, and that they had both made verbal denials to VLC, but were refusing to put their denials in writing.

I can understand that they might think that if they were to make written denials to me, then many other people with my condition might write to them with similar questions. But Ive asked a couple of journalists if theyve been writing about me, theyve made written denials, Ive believed them, and I have not put their denials on my website because, since I believe their denials, it would not be relevant to publish them.

To me it looks as if Lewis and Buerk are happy to lie verbally but not in writing, because written falsehoods would place them unambiguously in the wrong, whereas they can try to talk their way out of verbal lies if they are ever caught, or perhaps even deny the verbal lies completely? If they lie without shame, then why would they have any shame about future lies about lying?

One of the strangest aspects of "TV watching" is that Buerk and Lewis have convinced themselves that their "interactive spying" is reasonable behaviour. Martyn Lewis thinks of himself as a "gentleman". He expressed in 1992 that he was "on my side". If this matter ever comes out into the open, I wonder what these newscasters will have to say for themselves, and what the British public will make of their behaviour?

Media Persecution Evidence on my Website

You may directly access the Evidence section on my website at URL;

The category currently contains four video segments, a number of audio files and three published articles. The first video of ITN's John Suchet is unfortunately a mistake - after looking at it again it is obviously not about me. The two Ken Clarke excerpts may or may not be about me; it is funny that he should keep on harping about "paranoia" and "madness", but I have given these ratings of only 30% certainty, as it is more likely that they are not about me in particular, and Clarke is simply displaying the normal prejudices against the mentally ill found in much of society.

The piece I find most interesting is the Dimbleby/John Major interview from April 1997. I have assigned this a 90% rating. Dimbleby starts by emphasising a report from the "Knutsford Guardian". Major recognizes what's going on and joins in with a falsely apologetic "heaven forfend". The emphasis is on the first syllable pronounced "nuts" in "Knutsford", which is repeated three times. Of course this is hardly anywhere near convincing evidence; the really clear items were all in 1990-92, and they are basically unobtainable now.

If you're reading the website, have a look at the two files from David Hepworth's programme on GLR radio. The first one from 21/Feb/1997 has him

talking about an "embarassment" of prizes and "absolute obscene", in reference I believe to the verbal sexual abuse that was being used against me at the time (and which unfortunately is still current). In the second file dated 9/May/1997 he again talks about "absolute embarrassment" of prizes, followed by laughter. To my mind he knows I am listening to his programme, and deliberately makes these remarks for my benefit, with very little attempt to disguise their purpose.

Bernard Levin - "Fanatic's Fare for the Common Man"

On 21 September 1991 this article by Bernard Levin appeared in The Times. It is reproduced in the Evidence section of the website, or may be accessed directly at URL;

To my mind, Levin's article described the situation at the time and in particular a recent meeting with a friend, during which I for the first time admitted to someone other than my GP that I had been subjected to a conspiracy of harassment over the previous year and a half.

Levin writes about a "madman running loose about London" who "bursts into tears, and swears it is all true. And it is." I am pleased to agree with his assertion that "it is all true" because the truth is what I presented to my friend in September 1991 and it is what is being presented to the readership of these articles now.

Conclusion

The harassment, in particular media persecution, was at its strongest in 1990-92. Today, I am recording everything I watch, read and listen, and the media have pretty much given up. It is now incidents "in public" which make up what there is of MI5s persecution. But much of the material from 1990-92 still exists in archives, although the organisations which have those archives generally wont make the material available to the public, for copyright and other reasons.

MI5 can no longer employ the media to persecute me, partly because journalists now know who is behind the persecution, and also because I would publish any instances. My mistake during 1990-92 was to not record instances as they happened; Ive learned from that mistake, and know better now.

Ian White GM3SEK wrote:
> In practical terms, a lumped-inductance model will take you straight to
> a buildable prototype."

If you are a technician or a hobbyist, by all means
use the shortcuts. If you are an engineer or physicist,
to do so will lead your concepts astray.

Take the use of standing-wave current to try to measure
the delay through a 75m mobile loading coil. The results
of using the lumped-inductance model are off by a magnitude.
A 75m mobile loading coil is a distributed network that
is an appreciable percentage of a wavelength. As such, the
lumped inductance model is inadequate for analysis.

Here is a quote from my web page:

Many experiments and measurements have been made on loading
coils using net standing wave current. A lack of understanding
of the nature of standing wave current has resulted in some
strange and magical assertions about current through a loading
coil. The equation for standing wave current is of the form:

I(x,t) = Imax sin(kx) cos(wt)

For any point location 'x', it can be seen that the standing
wave current is not "flowing" in the ordinary sense of the word
but rather, is just oscillating in place at that fixed point.
EZNEC confirms that the phase of standing wave current is essentially
constant all up and down a typical HF mobile antenna and therefore
cannot be used to make a valid measurement of the phase shift (delay)
through a loading coil (or even through a wire.) The validity of that
statement is obvious if one understands the implications of the
standing wave current equation above. In fact, we can just as easily
write the standing wave current equation as:

I(x,t) = Imax sin(kx) cos(-wt)

We can reverse the direction of rotation of the standing wave
current phasor and still have the same value of current. Standing
wave current really doesn't have a direction of flow.

MI5 Persecution Update: Friday 19 March, 1999

If You Intend To Reply, Please Read This

Please.... keep your response to one page if you can! I have had several people faxing my article back to me, including one MP faxing back twenty pages. Faxes over a page or two will be deleted without being read.

Theyve started again. Why? I have no idea.

Unhappily, the persecutors, whoever they might be, have started their activities again over the last two weeks. Usually they try to blame their activities on their victim, but this time they have stopped even pretending that the persecution is my fault. Their verbal abuse appears as gratuitous as it is vicious.

Last Sunday 14 March, I went for a meal in Londons Chinatown with some friends. As we were walking down Gerrard St, a man shouted loudly, twice, the obscenity which has been directed at me for some three years now. This followed previous incidents where the same words had been used. It is very upsetting to be verbally abused in this way and to know that the cowardly abusers are guaranteed to "get away with it" because if you report it then it will be assumed to be part of your illness.

Keith Hill MP (Labour - Streatham), my elected representative, as ever refuses to help.

MI5 Persecution : How to Identify the Persecutors

Usually delusional thinking does not allow the perpetrators to be identified, or the alleged persecution to be proved. My so-called "delusions" are different, because I have several times over a period of some nine years seen the same people, in widely varying places. Most importantly, their names have been recorded, on aircraft passenger lists and hospital register; and if only the police would do their job conscientiously then the persecutors could be identified and this unhappy story brought to a final conclusion.

BA93 Heathrow->Toronto, 10 June 1993

In 1993 I flew to Toronto for a holiday. On disembarking from the aircraft, a group of four men who travelled together looked in my direction, and one of them said, laughing, "If he tries to run away well find him".

I was absolutely stunned when I heard this. I wasnt surprised that they had followed me to Canada, but it shocked me that they had been on the same flight, and that one of them had foolishly given their group away. Unfortunately I was so stunned that I made no attempt to stop them as they got off the flight and proceeded into the terminal. I did not see these people again during my visit to Toronto. I do not know whether they followed me, or whether they were only part of a larger group, some of whom may have already been on the ground and awaiting my arrival.

Over the next few years I made a number of attempts, all unsuccessful, to obtain the passenger list for this flight. British Airways keeps passenger flight coupons for each flight; so if only the police would do the job that is being asked if them, then these four persecutors could be identified, and thus their employing organisation, which is very likely to be the Security Service, determined.

These four men were, apart from the joker who looked the odd man out in the pack, very serious individuals. They appeared to be in their forties or fifties, and my impression on seeing them was that they might have been former soldiers. Their campaign against me concentrates on how "funny" their abuse is; but in this they are plainly lying, because they realise how awful will be the damage to the establishment of which they form part, if the truth about the persecution ever sees the light of day.

The riddle of "Alan Holdsworth"

During Oct/Nov 1996 I saw a doctor several times about an infection, and on 2 Nov 1996 I went to Emergency at the Ottawa Civic Hospital and saw Dr Worthington, who was then Chief of Emergency Medicine. I had to wait several hours before being seen, and several people jumped ahead of me in the queue. One of these was a grey-haired man in his forties or fifties. This may have been one of the men on the BA flight in 1993; I cannot be sure. When Dr Worthington asked his name, he loudly said, "Tad", which is the common abbreviation of my name. Dr Worthington looked puzzled, glanced at the sheet in front of him, and said, "but your name is Alan Holdsworth isnt it?". (I am pretty sure his Christian name was Alan; I cannot be sure of the surname). The man looked put out, and said quietly, "yes".

Unfortunately, I did not follow up this incident immediately. Some time later, I wrote to Dr Worthington to ask the name of this patient, but he refused to give the name out.

I saw this person again two and a half years later, at Ottawa Airport, just as I was about to leave for England. In the warm weather, he was wearing a coat and woolly cap, and pacing up and down in a menacing and aggressive manner. Presumably he thought he was pretending to be a "nutter" and in this way was getting at me; my impression is that he doesnt need to pretend, Holdsworth or whatever his name is is clearly a psychopath and in a healthy society such a person would be locked up, instead of being paid public money to exercise his psychopathic instincts. But todays Britain, a country where the MI5 secret police are given free rein and nobody dares raise a voice in protest, is not a

healthy society.

"He doesnt know who we are"

For some reason, whenever I take a British Airways flight, I get hassled by the "persecutors who wont admit theyre MI5". Since this business started, I have travelled BA three times; once in June 1993 BA93 (see above), once to/from Europe during Dec 95/Jan 96, and once in June 1998 with my mother to visit her family. The last journey, I was abused by two "plants" who kept repeating, loudly, "paranoid" (I have this recorded on minidisc). Presumably British Airways gives MI5 the seating plans for their flights, which allows MI5 to position their agents of abuse three rows behind me, so I cant face them, and they are throwing abuse at the back of my head. I have travelled BA as infrequently as possible; to Canada, I usually travel Air Canada.

Anyway, lets return to the second of the three BA trips, and in particular to the flight on 2 January 1996 from Berlin Tegel, to Heathrow, and onwards to Montreal Mirabel. Id waited all night at Tegel for the flight, and was very tired on reaching Heathrow. On the plane to Montreal, two youths sat about three/four rows behind me and to the right, in the window seats. One of them, a rather fat "asshole" to use the Americanism (it fits), kept on going on about "this bloke", saying among many other things, "he doesnt know who we are".

Now that form of words is particularly interesting, because from May 1995, some 8 months previously, I had been vigorously denouncing the "MI5 Persecution" on Usenet. So if Id guessed wrong, then you might expect the harassers to crow about it; which they have not done. If I had guessed right, and the persecutors have been silent before and since this flight, then they could either admit they were MI5, which would be a very serious thing for them to own up to, or they could brazenly lie, in which case I would report their lie, and since many people must surely know who they are, they would lose all credibility. So they have remained silent; apart from this one phrase on the BA flight, where one of their agents said, "he doesnt know who we are". Note carefully that this phrase is NOT a denial, it only appears to be a denial; since it does not say that my guess was wrong; it only states the objective fact that I do not know the identity of the persecutors, without giving any information as to the validity of my guess. Which leads me to posit that my guess was correct.

MI5 Persecution Update: Friday 25 March, 1999

If You Intend To Reply, Please Read This
Please.... keep your response to one page if you can!. Faxes over a page or two will be deleted without being read.

The Usual Words

The persecutors-who-wont-admit-theyre-MI5 have been active again this week. On Saturday 20/3/99 I visited Ravenscourt Park in west London, and was verbally assaulted with the usual words, "something wrong with him". This audio file is on the web at URL;

This afternoon (Friday 26/March) I was again verbally assaulted while travelling by bus. The same sexual obscenity was thrown at me, and the incident was recorded on my minidisc-walkman. Because of the deeply offensive nature of the slander, I will not be posting this on the website.

Keith Hill MP (Labour - Streatham), my elected representative, as ever refuses to help.

MI5 Persecution : Browse Website

The March 1998 issue (number 42) of .net Magazine reviews the website describing it as an "excellent site". Since August 11, 1996 over 50,000 people have browsed this website.

You are encouraged to read the web pages which include

a FAQ (frequently asked questions) section outlining the nature of the persecutors, their methods of harassment through the media, people at work and among the general public

an evidence section, which carries audio and video clips of media and workplace harassment, rated according to how directly I think they refer to me

objective descriptions of the state security agencies involved

scanned texts of the complaints I have made to media and state security agencies involved

posts which have been made to netnews over the last four years on this topic

This article outlines what is to be found on the webpages, which you are encouraged to browse for the complete story.

Frequently Asked Questions

Your excursion through the website starts with the "FAQ - Frequently Asked Questions" portion. MI5s campaign of harassment against me has been going on for almost 9 years, and its longevity and breadth is reflected in the FAQ. Many thousands of people in Britain and abroad, including some recipients of this fax, have known for many years of MI5s activities against me. The FAQ describes the mass "Omerta suppressing its publication"; we pretend Britain is part of the "Free World", yet the British Secret Police, which is what MI5 are, carry on for many years a campaign which politicians and the media know about, and rely on the silent complicity of so many thousands of people.

The FAQs introductory article names those who are "in the know"; media figures like Martyn Lewis, Michael Buerk, entertainment figures like Chris Tarrant, politicians and many in the general public, "all united in a conspiracy which breaks the laws which the UK does have regarding harassment, and all completely uncaring for any semblance of decency or elementary respect for individual rights.

Broadcast media play a key role in the harassment. The very first incident in June 1990 was when a television newsreader reacted to what she saw happen in my living room at home; such incidents of "interactive television" are still happening in 1999. The same goes for radio stations such as Capital FM. In spring 1994, Chris Tarrant on his Capital morning show made an aside to someone else in the studio, about a person he didn't identify. He said, "You know this bloke? He says we're trying to kill him. We should be done for attempted manslaughter". Tarrant and Capital have made strenuous efforts to avoid answering this charge.

Perhaps worst of all, MI5 have deliberately set-up many incidents in public places such as tube stations, shops, cinemas, where they have paid people to throw abuse at me. Since MI5 obtains funds to the tune of 160 million a year to fund its criminal activities, it has funds both to pay its operatives and to "buy" media figures and members of the public to take part in its campaign of persecution.

The Security Service are professional liars. They throw slanderous abuse, yet they refuse to admit out loud that they are doing so. When challenged about their activities through the Security Service Tribunal they lie and deny their activities. They induce other workers and managers at places of employment to take part in their campaign of abuse, presumably by buying them in the same way they buy media figures.

Complaints, and Press Coverage (BBC Lies, MI5 Lies)

As you might expect I have challenged both the Security Service, through the Security Service Tribunal, and offending broadcasters, to own up to what they have been doing. And as you might also expect, all of these people have lied through their teeth. Still worse, they have refused to commit unambiguous lies on paper; they have couched their lies in bureaucratic language, and allowed others to make false assurances and tell lies on their behalf. So when their lies are exposed, they will then tell further Clintonesque lies about how they werent really telling lies in the first place!

On 6/Feb/1997 the BBC told me they would "never engage in any form of surveillance activity such as you describe". The BBC told me Buerk and Lewis had refused to put their lies in writing, but had stated verbal falsehoods denying my accusations of "interactive watching" during news broadcasts. Clearly Buerk and Lewis fear being caught and exposed, so they hide behind their Viewer Correspondence department.

In March 1997 I issued a summons against the BBC to try to "smoke them out". This summons was struck out as "disclosing no reasonable cause of action", because I had acted as a Litigant-in-Person and most LiP summons are treated thus. My case was arguable in law, so the striking out was unjust.

In June 1997 the Security Service Tribunal wrote to me regarding the complaint I had brought against MI5 in February. They say, "The Security Service Tribunal have now investigated your complaint and have asked me to inform you that no determination in your favour has been made on your complaint." I think you can guess the contempt which I feel for the Security Service Tribunal, who have never made a determination against MI5, and act as merely a whitewashing body for the Security Service. Unsurprisingly in May 1997 the Interception of Communications Tribunal gave the same result.

The last few items of "Press Coverage" give details of mentions of the MI5 Persecution in various magazines and newspapers such as BBCs Ariel, the Observer and .net magazine.

Evidence

Some audio and video clips of evidence have been recorded. My weakness in this area is because most of the really unambiguous evidence would have been obtainable in 1990-92, but I wasnt taping anything at the time, and its very difficult to now obtain recordings from that period.

The audio clip "Life is so Hard" relates to harassment at my workplace in Canada. In the latter half of 1996, I was sitting near to co-worker Mark Lee, who kept coming out with words and phrases which showed MI5 were supplying him with data from my home life. For example, I would say something on the telephone at home, and the following day he would repeat verbatim what I had said. When Mark Lee saw I was recording what he was saying, he started to make his remarks more ambiguous, or make the obvious ones out of earshot of the recorder.

However, during the evening of 12 November 1996, at home in my apartment (flat to you UK-ers), I said "life is so hard, and then you die". A nihilistic, negative thing to say, but quite distinctive. The following day, 13 November, Mark said loudly, "life is so hard eh, and then you die" followed by loud laughter. I captured this on my tape-walkman and the computer-audio file is posted on the website.

There are a number of other audio files in the websites "Evidence" area demonstrating the abuse to which MI5 subject me to through their paid agents.

Also in this section is a very interesting article by journalist Bernard Levin, which followed a meeting I had with a friend in 1991, and to my mind describes in some details Levins "artists impression" of the meeting. He talks about a "madman" who "bursts into tears, and swears it is all true. And it is."

Internet Newsgroup (Usenet) archive

From May 1995 until the present day, this matter has been discussed exhaustively on internet newsgroups. The most interesting articles from the first two years of posts are documented here. This area is worth reading since most of the questions which the reader would ask, have been asked at some time or another by someone on usenet. Perhaps the very first article posted sums it all up so succinctly;

Date: Thu May 4 18:27:24 1995
Newsgroups: alt.conspiracy
Subject: BBC's Hidden Shame

Remember the two-way televisions in George Orwell's 1984? The ones which watched you back? Which you could never get rid of, only the sound could be turned down?
Well the country which brought Orwell into the world has made his nightmare follow into the world after him. Since 1990 the British have been waging war against one of their own citizens using surveillance to invade privacy and a campaign of abuse in the transmitted media in their efforts to humiliate their victim.
And the most remarkable thing about it is that what they do is not even illegal - the UK has no laws to protect the privacy of its citizens, nor does it proscribe harassment or abuse except in the case of racial abuse.
A lot of people in England know this to be going on, yet so far they have maintained perfect "omerta"; not a sound, not a squeak has escaped into the English press, and for all the covert harassment absolutely nothing has come out into the public domain.
Have the British gone mad? I think we should be told.

So how much deeper will the persecutors-who-wont-admit-theyre-MI5 sink in their campaign of lies and intimidation? Each time I thought they could sink no lower, they have managed to surprise me. You thought it could never happen here? When the MI5 British Secret Police make their smears against me, it is the corruption of the Establishment, which they are part of, that is demonstrated.

> Exactly. Why would anyone refuse?

Nobody has refused so it is a rhetorical question
the meaning of which is obscure.

> So the next question is: What is the phase change
> at the terminals of the black box?

You list the phase changes at the terminals of the
black boxes. An s-parameter analysis will prove those
are valid values. Have you done that s-parameter
analysis yet?

b1 = s11*a1 + s12*a2

b2 = s21*a1 + s22*a2

The phase shift is the relative phase between b1 and a2.
And also the relative phase between b2 and a1.

> 1) -93 degrees? (previous answer when it was a capacitor)

I might be wrong about that one. It might instead be
180 - 93, but that would just be a stupid math mistake.
The main thing is that it is different from the other two.

> 2) 36.6 degrees? (previous answer when it was 10 degrees of 100 ohm
> line)
> 3) 0 degrees? (previous answer when it was 46.6 degrees of 600 ohm
> line)

There's nothing wrong with those answers except maybe
a stupid math error. Each condition indeed does have a
different phase shift that can be measured one inch on
the other side of the terminals if one is simply allowed
to make those measurements. If s11 is measured and stamped
on the black boxes, the phase changes can be easily
calculated.

This is an example of how models can get you into trouble.
Not allowing us to look inside the black box doesn't change
the laws of physics and make all the phase shifts the same.
It just means that the phase shifts are unknown and need

to be measured.

Using that same logic, if you were shackled at the bottom of Carlsbad Caverns, night and day would stop happening just because you couldn't see it happening.

Do you really expect us to believe that the phase shift is the same for all the black boxes but changes abruptly when the reflection coefficients are measured?

Keith Dysart wrote:
> So the next question is: What is the phase change
> at the terminals of the black box?

It just occurred to me that you and I may be talking
about two different phases.

```
---Z01---+---Z02---

Vfor1-->|-->Vfor2

Vref1<--|<--Vref2
```

I am talking about the phase shift in the forward waves
across the impedance discontinuity, i.e. the phase shift
between Vfor1 and Vfor2. The list of phase shifts is
the phase shift in the forward voltages at the impedance
discontinuity. It is different for all the black boxes.

If you are talking about the phase between Vfor1 and Vref1,
then, yes, that phase is the same for all the black boxes.
It is impossible for it to be otherwise.

BBC newscaster Nicholas Witchell cant stop himself laughing

During 1990-91 there were very many instances of "interactive television" where newscasters and other TV presenters saw on a screen before them what was happening in my home, and reacted, frequently by laughing at me. During this period I unfortunately did not record these programmes. For the last year or two, I have been recording everything I watch, and there has been a drastic decrease in such incidents.

However, on occasion, television presenters do still engage in "interactive watching" and react to what they see. This has been evident with Jon Snow of Channel Four News recently - a particularly interesting case, since it has been established that he cannot be corrupted by money (it is well-documented that MI5 offered him a tax-free salary and he turned them down). I wonder what device MI5 are using to encourage him to do the "interactive watching"?

On Saturday 10 April 1999 at 7pm, Nicholas Witchell on BBC2 News reacted when he saw that I was watching the programme, and I have his reactions stored safely on videotape. I have watched this tape several times and I am entirely confident that my evaluation of his reactions is correct. For several minutes his upper lip quivered in mirth as he attempted to keep a straight face. Then finally his self-control evaporated through the excuse of a weak joke and his face collapsed into a grin.

The strange thing is that I dont know why he was laughing at me, what I had done recently to "deserve" to be laughed at. The MI5 persecutors usually manage to invent some justification as to why people should laugh at and/or abuse me ("hes an X", "it was so funny" etc), so Mr Witchell could have been laughing for any number of reasons. Perhaps he found the views I have been expressing in these articles amusing? I suppose if youre paid enough money and ordered to laugh then even the most innocuous thing becomes funny.

Jon Snow of Channel Four News cant stop himself smirking, either.

On 12 February 1999 I was watching Channel Four News presented by Jon Snow. As usual, I was recording the programme, so that if anything out of

the ordinary happened, Id be able to go back and watch it again.

Now, Jon Snow, by his own claim, is uncorruptible. He says he turned down an offer of a substantial tax-free salary from MI5 - they wanted to make him their mouthpiece, and he told them where to get off.

So you will be most surprised to learn that Jon Snow "interactively watched" me that evening, and on many other evenings. Approximately fifteen minutes into the programme, he announced that the US President would be making a live appearance at about 7.30pm; I looked at the clock on the mantelpiece; and Snow saw me looking at the clock, and visibly tried to suppress a smirk.

Uncorruptible, are you, Mister Snow? If not money, then why are you watching me, Mister Snow? Are they forcing you to watch me? Cant you turn the monitor off, Mister Snow?

Keith Hill MP (Labour - Streatham), my elected representative, as ever refuses to help.

Comparing the MI5 Persecution with German "Final Solution"

It might seem offensive to compare the mass murder of millions of civilians in wartime with the peacetime persecution of merely one person. Yet the comparison has been coursing through my mind for several years now, because the brutality of German intent to "sub-humans" is very much comparable to the brutality of British intent to someone they vituperate and term "not up to British standards". The methods may differ, but the persecutors mindset is the same.

The Germans first targeted the mentally disabled, too

During WW2 millions of ethnic Russians, Poles, Jews, mentally ill, gypsies and other minorities were rounded up and murdered in purpose-built camps by the German regime, in the name of "racial superiority". Fifty years on, the British Secret Police, MI5, instituted a campaign of mass hysteria; but in their cowardice, limited their activities to one single victim.

It is instructive to note that the early German "cleansing" effort was directed primarily not at Jews, but at the mentally ill. The Nazis set up the T4 project in the thirties to "cleanse" away 70,000 mentally disabled people, including schizophrenics and epileptics. After WW2 the Jews with their media influence used the reaction from the holocaust to roll back anti-semitism in the Western countries; however, the mentally ill are today still a persecuted group in the modern Western world as they were under the Nazis (the current Jewish home secretary in the UK intends to bring in laws for incarceration without any criminal charge for some mentally ill people - he protects his own minority, but does nothing for the other minorities in todays society), and this continuing bias forms a central cause for the current acts of persecution in the UK.

Widespread knowledge of what is happening to the "un-British" minority

In both the German persecution of the thirties and early forties, and the current British persecution, many, many people are well aware of whats happening. There is widespread complicity through inaction of populace; and in a substantial proportion of the mainstread population, the persecution had/has widespread enthusiastic support; yet in both the German case in the 1940s and the British today, the existence of persecution is a mass secret which must be never admitted out loud. In the recent Lawrence case this "secret bigotry" has been termed "institutionalised racism", and that is a very good word for what the British are doing today The persecutory attitudes and omerta regarding them are so deeply ingrained in the national psyche that they define the national mood

During WW2 many Germans knew minorities were disappearing, and through inaction quietly condoned their government's mass murder of "un-German" minorities and inferior "foreigners"; and in the 1990s, similarly, many English people know what the MI5 British Secret Police have been doing, and not only condone it, but actively take part, because of xenophobia against the "un-British" unit minority that is the target of "British" actions. This attitude by the British persecutors has been made explicit through the words "he's not up to British standards"; the British seem to have found their very own "untermenschen" to victimise.

Why these obsessive "holy wars" happen

This type of aggression occurs when the majority is threatened or humiliated in some way, economically, militarily or culturally. In pre-WW2 Germany the threat was primarily economic and military, following Germany's humiliating defeat in the first world war and the reparations it was forced to pay. In modern Britain, one might guess that the majority English who are behind the persecution feel pressured by the swiftly diminishing status of Britain in the world, and the rapidly increasing coloured colonisation of their country, which in time will see the ethnic English a minority in their own land, and their more antisocial elements, unable to reply to the obvious threat, instead project their aggression onto another, weaker, unit minority

In both cases there is a whiff of "holy war" or irrational obsession with the persecution. Certainly the German behaviour fifty years ago bordered on the not-quite-sane, and the current British behaviour towards their chosen victim is strongly tinged with a leave-taking of reason. And the choices open to the victims are the same, since MI5 will never allow me to escape them, "if he tries to run away we'll find him", just like the commandant of Auschwitz telling the new arrivals, "the only escape is through the chimney".

The Victim Will Destroy Us if We Dont Destroy Him First

The persecutors propaganda is the same. Fifty years ago the Germans said, "if we don't do it to the Jews then the Jews will do it to us"; and MI5's propaganda in the early nineties concentrated on their victim as a "monster" aesome "untermenschen" minority.

"We are decent fellows" say the Brutal Persecutors

During the course of researching this article I read part of the very interesting book, "Hitler - A Study in Tyranny", by Alan Bullock. This volume contains a quote from Himmler on the "Final Solution";

"Most of you know what it means when a hundred corpses are lying side by side, or five hundred or one thousand. To have stuck it out, and at the same time .... to have remained decent fellows, that is what has made us hard. This is a page of glory in our history which has never been written and is never to be written."

In the MI5 persecution, too, there is a thread of deliberate brutality to the sick and vulnerable, while the persecutors maintain that "we are decent fellows". There is almost a conscious schizophrenia in the self-attitudes of the Security Service operatives and those in the public who they employ against me, which reflects the contradiction evident in the German attitude above. On the one hand, they stoop to the lowest and most base behaviour; yet at the same time, the MI5 operatives tell themselves that since they are civilised British people, then surely they must by definition be "decent fellows". Any indecency is made the fault of the victim; "hes making us persecute him, so we need feel no guilt".

Yet the conduct is atypical of the way these peoples see their normal modes of behaviour. Befslaughter was not typical of normal German behaviour up to that point. Similarly, the current MI5 abuse goes against the grain of British self-image as being "reserved" and "decent", since they are using terms of abuse which are common among blacks and other supposedly less-developed races, but not among the English.

Conclusion

The ultimate aim of both persecutions is the humiliation and physical extinction of the persecuted group. The Germans did this in a very direct way; the British Secret Police MI5 are acting indirectly and relying on self-extinction of their target, because in peacetime and in the current somewhat false climate of "political correctness" more direct methods are impossible. If MI5 undertook more direct action the mass "omerta" would be broken.

I have written this article with sincerity to show how a historically recent persecution in another country parallels what is being done in this country today. In both cases, the evil-doers are of their countries establishments, and rely on widespread tacit support to maintain the persecution and omerta around it. While the holocaust was undoubtedly the greater evil, it is important to be aware of the fact that had the Germans not been defeated fifty years ago, their plans would have gone through to total completion. In Britain today no force threatens the "permanent government" of which the Security Service forms a part; and it looks very unlikely that the wrongs perpetrated by the MI5 secret police will ever be revealed to public view, and the British secret state brought to justice for its evil actions.

MI5 Persecution Update: Friday 30 April, 1999

If You Intend To Reply, Please Read This
Please.... keep your response to one page!. Faxes over a page or two will be deleted without being read.

Somewhere between 0 and 100%

The last few days there have been no clear recordable instances of abuse. However, while travelling on the Underground, while walking around near my home and going to friends homes, I am constantly troubled by thoughts that those people over there might be about to get at me; that the couple sitting in the opposite seats laughing are in fact laughing at me; et cetera, et cetera.

A comment by a scientist to the BSE inquiry sticks in my mind. He described the possible scale of the epidemic as "between 0% and 100%". It might not be happening, it might not happen at all, to any discernable degree.... or it might be total. Without clear recording, which seems to have become impossible the last couple of weeks, there is no way of knowing whether the harassment really is continuing, whether we have entered a temporary hiatus, or whether perhaps it has perhaps stopped for now.

But for the time being I think there arent any reasons to dicontinue these faxes. I only re-started them six weeks ago in response to a resumption of MI5 harassment; and I think I will need to be more convinced of absence of persecution before I discontinue my complaints.

The Newscasters are still watching

In the last few weeks there have been at least a couple of fairly overt instances of "interactive watching" by newscasters. I reported this in a previous "MI5 Persecution Update".

These instances are really very rare compared to 1990-91, when there were many dozens of such occurrences. Undoubtedly the reduction is due to my practice of videotaping everything I see. Recently I had the opportunity of showing this years "happenings" (Jon Snow/Nicholas Witchell) to my psychiatrist, and he agreed that in both cases the newscasters were expressing merriment without visible cause, and that objectively it might be possible for my claims to be true - although of course other people reported similar thoughts to him, and this thinking is usually a symptom of illness.

Read About the MI5 Persecution on the World Wide Web

The March 1998 issue (number 42) of .net Magazine reviews the website describing it as an "excellent site". Since August 11, 1996 over 50,000 people have browsed this website.

You are encouraged to read the web pages which include

a FAQ (frequently asked questions) section outlining the nature of the persecutors, their methods of harassment through the media, people at work and among the general public

an evidence section, which carries audio and video clips of media and workplace harassment, rated according to how directly I think they refer to me

objective descriptions of the state security agencies involved

scanned texts of the complaints I have made to media and state security agencies involved

posts which have been made to netnews over the last four years on this topic

Keith Hill MP (Labour - Streatham), my elected representative, as ever refuses to help.

MI5 Waste Taxpayer Millions on Pointless Hate-Campaign

Recently I was talking to an independent observer about the nature and purpose of the perceived campaign of persecution against me. The person I spoke to, a highly intelligent man, said he was struck by the utter pointlessness of the perceived campaign against me. He also said that, if my theories were in fact true, many people would have to be involved, in the surveillance itself, and in the technical side of the delivery of information from my home to TV studios for example, if the "interactive watching" were happening as described. He voiced these thoughts without any prompting from me; but both I and other observers had arrived at pretty much the same conclusions, some years ago.

I saw a team of four men at Toronto Airport in 1993

To carry out the surveillance alone, full-time, would employ four or five men, or their equivalent in terms of man-hours. Each man would "work" an eight-hour shift, so you would need at least three men doing the surveillance, plus a connecting link / manager. An indicator that this estimate is correct arrived in 1993, when I was accosted by one of a group of four men at Toronto Airport; he said, laughing, "if he tries to run away well find him". Plainly these were the men who had been involved in the intrusive surveillance of me for the preceding three years.

On other occasions, I have seen the same man on two or three occasions. On one such occasion, at Ottawas Civic Hospital in November 1996; he gave his name to the doctor as "Alan Holdsworth" or some such; my hearing is not very good sometimes and I am not sure of the surname, although I am sure "Alan" was his first name. I saw exactly the same man again in Ottawa, at the airport, in July 1998. Obviously, other people must be "working" with

this person; he would not be the sole agent employed in this case.

Usenet readers views on the Cost to MI5 of Running the Campaign

Here's what a couple of other people on internet newsgroups / Usenet (uk.misc) had to say regarding the cost of running such an operation...

PO: >Have some sense, grow up and smell reality. What you are talking about
PO: >would take loads of planning, tens of thousands of pounds and lots of
PO: >people involved in the planning, execution and maintenance of it. You
PO: >must have a very high opinion of yourself to think you are worth it.

and......

PM: >But why? And why you? Do you realize how much it would cost to keep
PM: >one person under continuous surveillance for five years? Think about
PM: >all the man/hours. Say they _just_ allocated a two man team and a
PM: >supervisor. OK., Supervisor's salary, say, #30,000 a year. Two men,
PM: >#20,000 a year each. But they'd need to work in shifts -- so it would
PM: >be six men at #20,000 (which with on-costs would work out at more
like
PM: >#30,000 to the employer.)
PM: >
PM: >So, we're talking #30,000 x 6. #180,000. plus say, #40,000 for the
PM: >supervisor. #220,000. Then you've got the hardware involved. And
PM: >any transcription that needs doing. You don't think the 'Big Boss'
PM: >would listen to hours and hours of tapes, do you.
PM: >
PM: >So, all in all, you couldn't actually do the job for much less than
PM: >a quarter million a year. Over five years. What are you doing that makes
PM: >it worth the while of the state to spend over one and a quarter million
PM: >on you?

Those are pretty much the sort of calculations that went through my head once I stopped to consider what it must be costing them to run this operation. At the very least, a quarter million a year - and probably much more, given the intrusive and human-resource-intensive methods employed. Times nine years. Equals well over two million pounds - and probably much, much more.

Its wasteful for someone with my skills to be unemployed

The wastefulness of the MI5 campaign against me is not just that of futile expenditure on their side. It is also extremely wasteful for someone with my talents to be unemployed and on a disability pension. I am highly qualified in numerate disciplines, yet am unable to work, specifically because of the MI5 hate-campaign against me. It is a terrible waste of resources for a supposedly efficient economy like that of the UK to be squandering the talents of a skilled and capable worker.

I made every effort to remain in employment for as long as I could, but ultimately I was defeated by MI5s employment of massive resources specifically targeted on my workplaces with the sole aim of seeing me

evicted from those workplaces. You might expect this sort of behaviour from the Stasi or some other secret police force in a communist country where labour is cheap, and the governments aim on seeing its citizens confined; but for a supposedly free and efficient economy like Britains, the wastefulness resulting both directly and indirectly from the Security Services activities is simply criminal, and should never be allowed.

The international dimension means the costs are multiplied many times overoer had any sense, then they have surely taken leave of them over the last nine years.

Four years of persecution in Canada

The persecution re-started within less than five minutes of my arrival in Canada, as documented above, and in the "frequently asked questions" article on the website. The words, "if he tries to run away well find him" spoken by one of the harassers at Toronto Airport are now imprinted on my mind.

A year later I emigrated to Canada, intending to find a job and settle there, hoping that MI5s interest in me might dim with time. I did manage to find work there, but my hopes of avoiding Security Service interest were ground into dust. As detailed above, I saw the same man in November 1996 and July 1998, both times in Ottawa. Apart from these encounters, there were numerous incidents between 1994 and 1998 of harassment, of an identical nature and in most cases using identical words to what had occurred in the UK. It became quite clear to me that the permanent surveillance and harassment operation which MI5 had subjected me to in England was being continued.

For a team of four or five men to be employed overseas must cost a lot more than if they operate in their home country. And for MI5 to continue the operation for a period of over four years, continuously, must cost many hundreds of thousands of pounds. This confirms my belief that the state is funding the campaign against mehat the Security Service receives current annual funding of #160M. Divided by 1850 staff, works out at #86,000. But the unit annual cost of each "watcher" must be much higher than this, especially given the frequently mobile and overseas nature of their actions of the last few years. A very conservative figure might be a little over #100,000 pa for each of a team of five people, or half a million pounds per year. For nine years, so far. So the most conservative estimate of the surveillance element alone is perhaps four or five million pounds since 1990.

This guesstimate is of course theoretical - I am not privy to inside details of how MI5 split their funding. But to take some other examples, the cost of a US counter-surveillance specialist per day is USD 5,000. Even if the agents permanently assigned to me are not of this calibre - even if they employ specialists when difficult work planting bugs etc is encountered - their salary and support costs must still be very high. The individual agents are doing well for themselves as they are well-paid to exercise psychopathic instincts which in any sane society

would see them in prison; but the taxpayers who must fund this terribly wasteful exercise are being "done" out of hundreds of thousands of pounds each year.

It must be emphasised that the above estimates are highly conservative. Besides the surveillance operation, it must carry a high cost in man-hours to propagate covert slanders through the population; to setup and maintain the "interactive watching" links to TV and radio stations, which these organisations continue desparately to "lie and deny"; and to induce antipathy in co-workers which would not otherwise exist.

Why they are wasting Millions of Pounds on a "Nobody from South London"

As remarked in the prologue to this article, it is really most extraordinary that the Security Service spends a chunk of its budget, every year for nine years so far, on a meaningless campaign against a "nobody from South London". That they are spending such a large amount of money has been confirmed to me on several occasions, usually by oblique references to "its costing this country millions". The supposed "logic" behind the persecution is that MI5 wish to avoid their harassment of me, and the involvement of the UK media, to be made public; yet as the reader will appreciate that is a circular argument, "theyre doing it because they want to keep it secret and avoid humiliation for themselves and their country" begs the question, "why did they start doing it in the first place?", to which in truth I myself do not know the answer.

Plainly MI5 with its rich budget can afford half a million pounds a year to waste on a "nobody from South London". Some time ago I was talking to a British surveillance professional on Compuserve who told me "this work costs a lot of money and is usally because the person I am following has done something (usually criminal) to warrant all this money and time being spent." Yet in this particular case it is plainly not the "victims fault" that the harassment is taking place. The hate-campaign against me is completely the creation of the obsessive psychologies of the MI5 agents who have made themselves my persecutors; it is obviously a "personal" campaign for them, and for years they misuse taxpayer funding to feed their insane, unnatural and fixated fantasies.

Four Years of "MI5 Persecution" Posts on Internet Newsgroups

For approximately the first three years of the MI5 persecution, from June 1990 until late 1992, I kept as quiet as possible, in the hope that by not reacting, MI5s interest in me would decrease and they would simply go away of their own accord. This is the sort of behaviour some people employ against bullies; if the bullies arent getting a reaction, then they might simply go away and victimize someone else.

Unfortunately, this tactic didnt work. The quieter I became, the more shrill and hysterical the noise from the Security Service operatives. For about two years I didnt watch TV news at all. Yet this only heightened their obsessed fixation; they continued to follow me wherever I went, they continued to induce harassment at work by managers and fellow workers, and they continued to encourage me to commit suicide. They seemed to regard my refusal to react as a crime which they would have to "put right" by ever more extreme forms of abuse.

Finally, in 1995, I changed tactics radically. Since late 1994 I had had accounts with internet providers in Ontario, Canada. I discovered the cornucopia of internet newsgroups, on every topic from consumer electronics, to politics and legal topics, and I discovered online services such as Compuserve and AOL. In May 1995, I made the first posting to the conspiracy newsgroup, on the subject of "BBCs Hidden Shame".

BBC's Hidden Shame

The internet newsgroup discussion, which has now reached its fourth anniversary, started with an article in alt.conspiracy, which I reproduce here.

Date: Thu May 4 18:27:24 1995
Newsgroups: alt.conspiracy
Subject: BBC's Hidden Shame

Remember the two-way televisions in George Orwell's 1984? The ones which watched you back? Which you could never get rid of, only the sound could be turned down?

Well the country which brought Orwell into the world has made his nightmare follow into the world after him. Since 1990 the British have been waging war against one of their own citizens using surveillance to invade privacy and a campaign of abuse in the transmitted media in their efforts to humiliate their "victim".

And the most remarkable thing about it is that what they do is not even illegal - the UK has no laws to protect the privacy of its citizens, nor does it proscribe harassment or abuse except in the case of racial abuse.

A lot of people in England know this to be going on, yet so far they have maintained perfect "omerta"; not a sound, not a squeak has escaped into the English press, and for all the covert harassment absolutely nothing has come out into the public domain.

Have the British gone mad? I think we should be told

At this point, I did not name MI5 as my persecutors. I was still unsure that they were the ones responsible for the "psychological terrorism". In followup posts however I did name them; and the persecutors have never denied the claim; so I think my guess is valid. (The Security Service Tribunal in 1997 have said "no determination in your favour was made", but it is a well established fact that MI5 lies routinely to the Tribunal which has never found in favour of a plaintiff, so no conclusions can be drawn from this.)

This first post was made to alt.conspiracy, but further posts were made to the UK-local newsgroups, in particular uk.misc but also uk.legal and uk.politics (which is now called uk.politics.misc). Some time ago I tried to take the battle to the Compuserve forums, UKPOLITICS (which is now called UKCURRENT - current affairs), but my articles were censored by the forum operators. Such censorship is impossible on the internet newsgroups.

Police Refuse to Act

I have complained several times to the Metropolitan Police, who have each time refused to help.

From: Green <Green@guidion.demon.co.uk>
Newsgroups: uk.misc,uk.politics,alt.politics.british,soc.culture.british
Subject: Re: MI5 Persecution: Why Aren't the British Police Doing Their Job?
Reply-To: Green@guidion.demon.co.uk
Date: Sun Apr 7 21:13:30 1996

In article <DpIE0r.736.0.bloor@torfree.net>
bu765@torfree.net "Mike Corley" writes:

>Last Easter (1995) I went into the local police station in London and spoke to
>an officer about the harassment against me. But I couldn't provide tangible
>evidence; what people said, in many cases years ago, is beyond proof, and
>without something to support my statements I cannot expect a police officer to
>take the complaint seriously.

This in itself dos not suggest that the police have it in for you. The old bill operates on extremely tight spending limits forced on them by that pillock Michael Howard, and without evidence, they often have higher priorities than chasing something that cannot go to court.

I doubt that the police are actually being leant on, but they probably realise that if they looked into this, they would be leant on hard. The met always stays away from anything that looks like it has Defence, Security or secret service interest already,

because they realise that they are below these government agencies in the general pecking order.

If I walked into my local nick and complained that MI5 were snooping on me, they would show me the door without even looking at my evidence, because that bored desk seargant with only five years to go before he retires doesn't want to start fucking about with somebody who has incurred the wrath of Stella Rimington. He would rather deal with the lost dogs and driving licence producers, eat his cheese and pickle sandwiches and piss off home at the end of his shift than have some high ranking spook having a go at his boss and getting him a bollocking.

In short, you have earned much sympathy but little surprise. Just remember that saying about the enemy of your enemies.

Most recently, I wrote in March 1999 to Charing Cross Police Station CID. They did not acknowledge or reply to my letter. When I phoned them up, the detective Id written to treated me to a sadly not unusual display of police bigotry, with an uneducated rant about "your paranoid rubbish".

It would be nice to think that such uneducated bigotry is something other than wholly typical of police behaviour, but unfortunately that is an illusion that is rapidly dispelled.

Uncorruptible Jon Snow of Channel Four News

From previous articles the reader will know what I think Jon Snow has recently been watching me while he reads Channel Four News in the evening. Recently I digitized a few moments of one such broadcast, where his face twists into a smile, without there being anything in the news broadcast to cause merriment. Here is a usenet post from some time ago on MI5s "bought and paid for" tools in the so-called "free" press.

Peter Harding (harding@ermine.ox.ac.uk) wrote:
: I was at speakers' corner on Sunday. There was one chap who was bellowing
: about something or other, I don't know what, but one thing he said to
: someone caught my ear:

: "BBC, MI5, same thing."

Can't disagree with that sentiment.

Wasn't it documented that MI5 sometimes "bought" journalists and broadcasters?
I remember reading a report by some jouralist who had been offered an extra
tax-free income by MI5 to become their covert mouthpiece, and had refused.
.....
> : >mouthpiece, and had refused.
> :
> : It was Jon Snow of Channel 4.
>
> Was it reported in any of the papers?

It has been reported several times. The most recent was in Private Eye, a few months back. As I recall they also wanted information from him; journalists would be a natural choice for members of the Security Service

and the Secret Intelligence Service for information sources.

> It might be interesting to see what he had to say regarding their
> attempt to recruit him.

He was most concerned that many others would have accepted such an offer. However, we can probably make an educated guess as to some of those who accepted: Nigel West (Rupert Allason, MP) and Chapman Pincher would come near to the top of the list.

Corrupt Security Service agents steal millions from taxpayers

Money is of course a factor in the grand equation which is the MI5 persecution. It costs money for the Security Service to "buy" people in the media etc. But that is only a small part of their expenditure of taxpayers resources. Most of the expenditure is directly on the salaries if the agents involved; and in this post I put forward the theory that MI5 are trying to draw out their involvement for as long as possible, very cynically, to maximise their income and line their own pockets.

At each stage they have tried to pretend that I am something out of the ordinary. Either I was very stupid ("he's an idiot") or very clever ("he's like a genius"). Either I was a threat to Western civilization (Levin once referred to me as the next Hitler) or I was completely defenceless ("a soft toy").

Now, it should be obvious to any person with common-sense that I am not out of the ordinary in any way. I have an IQ which is average for the Web, I am racially white European, and there are plenty of other people with schizophrenia or epilepsy out there who haven't been targeted for MI5 attention, so why me?

I think the answer is that the MI5 agents who harass me have cynically exploited the situation by painting me as extraordinary in order to assure themselves of well-paid employment funded by the ordinary British taxpayer. To put it bluntly, they are stealing millions of pounds from the taxpayer to feed their own pockets.

This assertion is supported by the observation that it's the same agents who are doing the harassment. Six months ago in a local hospital I was harassed by someone whose face I had seen (he had stared straight at me aggressively, at the time I just thought it was some nutter but it turns out he was one of "them") aboard a KLM flight a couple of years ago. It's presumably been the same people most of the time. I've seen the way contractors act when they don't want their positions terminated. Would these agents really want to lose their well-paid employment harassing me? Presumably they are promising their bosses a "breakthrough" (ie my demise) real-soon-now and have been for the last seven years, while all the while these MI5 agents skim millions

off the taxpayer.

I wouldn't mind a job like that. Perhaps if I persecute myself a little bit, like standing in front of a mirror and shouting mindless obscenities, do you reckon I'd get a slice of the caky Service Tribunal. This year Nick Brooks, current Tribunal Secretary, confirmed to me that he could not think of a single case where the Tribunal had found in favour of a complainant. Here is my usenet post from two years ago.

Subject: MI5: "It wasn't us"
Newsgroups: uk.misc,uk.legal
Organization: Toronto Free-Net

"The Security Service Tribunal have now investigated your complaint and have asked me to inform you that no determination in your favour has been made on your complaint."

Signed ER Wilson, Tribunal Secretary

Well that's a relief then. All that spamming for nothing eh. Gaw blimey, if they say they're not doing it then it can't be them, can it?

In a recent letter to Mr Brooks I expressed the opinion that the Tribunal were unable to fulfil their responsibilities in the face of MI5 falsehoods. Nevertheless, I do intend to make another complaint to the Tribunal in the near future, despite the Tribunal appearing to be a toothless watchdog.

Discrimination against a Unit Minority

MI5 have been very clear in their instructions as to what I should do. They have openly shouted at me the word "suicide", and also from the other abuse it is clear that they want my existence terminated.

This point is covered in more detail in a previous article. The following post describes the xenophobic nature of MI5s campaign against me. They have refined their bigotry down to a unit minority, yet they make use of the discrimination against the mentally ill which is a feature of current British society.

>Indeed. If you've ever had a 'conversation' with someone suffering
>from florid schizophrenia, you'll know how difficult it can be to
>'argue' with them.

I don't have florid symptoms. But I'm in a difficult situation, because those people who don't know, aren't going to believe, and those who do, they just go

along with the crowd. It's never a good idea to go against the grain, and the grain here is defined by interests in the establishment and the media. Even people who could say out loud what was happening won't, because then there's a risk that they'll be seen as traitors and ostracised.

Usually this type of 'hidden abuse' is racial and targetted at a racial minority within a country. You keep the minorities out of the good jobs, but you don't admit discrimination exists. It happens everywhere, not just in Britain. The persecution that is going on now is in reality a refined form of racism. Instead of "nigger" it's "nutter", and abusing the mentally ill is still socially acceptable today. In 50 years it might not be, but today there isn't any social or legal sanction against it.

So really they've refined racial harassment down to a minority of one. The words may be different, but the methods are the same.

MI5 Persecution: BBC Newscasters Lie & Deny They're Watching Me

Central to the persecution campaign waged against me for some nine years now by the Security Service is their use of the media, and in particular the broadcast media, to make clear to me that I am under surveillance and being watched within my own home, even by BBC newscasters while they read the news. This is really an act of arrogance; MI5 and their tools in the television and radio are so sure that they can never be caught, that they have many times made explicity clear on broadcast programmes that they are as capable of seeing me as I am of seeing the broadcast pictures. Even when they have known I am taping the programmes they still carry on this practice; for examples of TVand radio presenters caught "in action", see the Evidence area of my website.

If you wish to reply to this article......
then please include your name and fax number! I provide the means for recipients to send me their thoughts on the topics discussed, but ask that you provide me with your fax number or email address if you require a response. Also would you please send not more than one or two pages, if by fax. Thank-you!

It started with a Newscaster, and it continues with Newscasters today

The very first incident in the story started with a reaction by an ITN newscaster, Sue Carpenter, in June of 1990, almost nine years ago now. She reacted to what she saw in my living room at home as she read the news. My mother had brought an apple for me into the room, whereupon the newsreader smirked and giggled, apparently finding this funny. I couldn't believe what I was seeing. I carried on watching news and other television programmes to see if presenters would show signs of "interactive watching"; to my surprise, this happened again and again. Unfortunately, I did not have my wits sufficiently about me to videotape these programmes, and it is now almost impossible to obtain recordings dating back to 1990.

However, I have been busy recording everything Ive watched the last couple of years, and the taping has yielded some nuggets, which you will find if you point your Web browser at the "evidence" area of my website, whose URL address is given above. Strangely it is not particularly the BBC who are "after me" at the moment (with the exception of occasional fire from Nicholas Witchell), but that supposed paragon of virtue and decency Jon Snow of Channel Four TV News (he actually works for ITN), who once claimed hed turned down MI5s offer of a tax-free salary. I will cover Snows recent actions in a future article.

BBCs Hidden Shame

The first ever Usenet post (internet newsgroup article) on the subject of the MI5 bugging / BBC watching occurred, as stated in a previous article, in early May 1995. It is reproduced here;

Date: Thu May 4 18:27:24 1995
Newsgroups: alt.conspiracy
Subject: BBC's Hidden Shame

Remember the two-way televisions in George Orwell's 1984? The ones which watched you back? Which you could never get rid of, only the sound could be turned down?

Well the country which brought Orwell into the world has made his nightmare follow into the world after him. Since 1990 the British have been waging war against one of their own citizens using surveillance to invade privacy and a campaign of abuse in the transmitted media in their efforts to humiliate their "victim".

I suppose "BBCs Hidden Shame" is more of a wish than a fact. It may be hidden, but the BBC and other media and security organisations seem to have no shame whatever in their anti-social, not to say criminal, actions. Nor do the general public, who seem quite happy to parrot the vilest obscenities without much hesitation or apparently thought.

Martyn Lewis, Nicholas Witchell and the rest

Most of the harassment occurred in 1990-92, when I wasnt making any recordings, and the BBC wont release copies of current affairs programmes from that period.... so although I can remember there were many incidents in that time, even many specifics, I cant dig up the actual programmes to flesh out the bones.

This year, there has been at least one incident with Nicholas Witchell as newsreader, which I have successfully recorded and digitized, i.e. converted into a computer Quicktime movie file. This has not yet found its way onto my website (Im a busy man, dontcha know) but you can be sure I will let the readership of these articles know when that clip makes it onto the web. The Witchell clip was recorded on Saturday 10 April 1999 at 7pm, and shows Witchell trying to restrain his features from collapsing into a smirk. First his upper lip quivers for several minutes, then with the non-excuse of a non-joke his entire face twists into a grin. It looks as if he finds me so funny, that he allows himself to submerge any pretence at professionalism in a sea of MI5-inspired sarcasm and harassment.

The two BBC newscasters whose reactions to me I can remember most vividly over the years are Martyn Lewis and Nicholas Witchell. I can remember thinking years ago that Michael Buerk was also seeing me at home; and if the other two are watching then there would be no reason why he wouldnt be doing the same; but in all honesty I cannot remember a single clear instance of his reacting through facial or verbal expression to me.

I can remember several instances of Martyn Lewis reacting to what he saw of me, however. In early 1992 I was watching the BBC news with Lewis on a small black-and-white portable TV at my then home in Oxford. I threw a term of abuse at Lewis; he flinched, then gave a grin and made a comment from which I understood that he had been on my side, but might have changed his mind as a result of what Id just said to him.

And in spring 1991 I remember Martyn Lewis clearly reacting to what he saw of me at my then accommodation in Woking, Surrey, by continuing to stare at some fixed point near the camera after the news had finished - presumably this is where the monitor interactively showing pictures of my room was located.

Why would BBC and other Newscasters Watch and Harass Me, Watching Them?

This is a very difficult question, and I dont actually know the answer. It is a matter of record that the Secret Services are very much part of the Establishment. The recent exposure of the "MI6 Agent List" on the internet, and its coverage in the newspapers, reveals how much MI5 and MI6 are recruited from the ranks of the Establishment. Obviously the relationship is bi-directional; the Establishment influences MI5/MI6, but the secret services (well, perhaps not so secret now we know who works for MI6!!!) also influence the machinery of power and information dissemination i.e. media in this country. So they must have a lot of covert leverage with the BBC and ITN.

Some of this leverage is obviously through bribery. It is a matter of record that MI5 tried some years ago to "buy" Jon Snow of Channel Four TV. He turned them down - obviously they must have approached other media people as well, and from the lack of other reports of people turning them down, it may be presumed that some other journalists will have accepted the sugared carrots put before them. Ironically, Jon Snow has been taking part in the recent "watching" actions against me - but why he has allowed himself to be used by the secret services is something which I do not know.

Perhaps the Security Service uses blackmail to twist arms of journalists into co-operating with them? I have always thought there was something slightly odd about Martyn Lewiss demeanour. At the time of the Ron Davies "rough trade" scandal it was reported that MI5 had known all about Davies predilections and the sham of his pretence to be a happily married man. Perhaps MI5 have been able to dig something up from Martyn Lewiss private life to blackmail him into acting on their behalf? And if there wasnt anything before the "newscaster watching" started then there most certainly is something now.... once theyve started watching, the newscasters will surely wish their activities to remain covered-up, and co-operate with the security service.

"Newscaster Watching" Deliberately Constructed to Mimic Schizophrenia

Presumably this is the first case in history of television journalists actually taking part in acts of real-time, live spying and reacting against one of their viewers. What you have to understand, though, is that

I was quite mentally healthy in June 1990, certainly relative to November 1992, when after two and a half years of harassment I was finally admitted to hospital as an out-patient. MI5 decided from the outset that they would make me mad; they constructed the media harassment to resemble what would be reported by a person with mental illness; and then they carried on years of abuse to inflict on me the condition which they wished to use as an excuse to cover up their abuses.

I sold my portable TV in autumn 1990 and stopped watching television regularly. I realise now that this may have been a mistake. What I should have done was to watch TV and listen to the radio, but tape-record everything and make a note of what each excerpt meant to me. I would then be in a much stronger position as regards to evidence that I am now. That is what I am trying to do now, but unsurprisingly the TV/radio presenters have stopped getting at me, now they know they are being recorded.

When I started publicising my case on internet newsgroups in 1995, I was met with the disbelief one might expect to be accorded to a mentally ill person who talks about "newscaster watching" and media persecution. Some newsgroup participants thought I had started a "troll", an invention made to obtain a reaction; one bright spark even suggested a group of psychology students were behind the articles. But most people thought the articles were symptomatic of derangement - and that is exactly what MI5 want people to think. MI5 chose me as a target because I was mildly mentally ill at the outset in 1990, although I stress my illness then was very mild in comparison with November 1992, and because they knew that enough abuse would (a) make me much more seriously ill, and (b) once I was more ill, they would "get away" with a harassment deliberately constructed to look like the symptoms of paranoid schizophrenia.

Martyn Lewis Denies & Lies, But Wont in Writing

In February 1997 I wrote to BBC Viewer & Listener Correspondence and asked them to investigate the claim that their newscasters had engaged in "real-time spying" on me. They replied that they had asked Martyn Lewis and Michael Buerk whether they had engaged in such practices, and that they had both made verbal denials to VLC, but were refusing to put their denials in writing.

To me it looks as if Lewis and Buerk are happy to lie verbally but not in writing, because written falsehoods would place them unambiguously in the wrong, whereas they can try to talk their way out of verbal lies if they are ever caught, or perhaps even deny the verbal lies completely? If they lie without shame, then why would they have any shame about future lies about lying?

BBC-VLC also said that the BBC "would never engage in any form of surveillance activity" such as that described. Clearly Martyn Lewis and the rest have lied to their own organisations personnel about their criminal actions. So much for the "objective", "truthful" BBC, a nest of shabby liars.

Summons against the BBC, for Nuisance caused by Newscaster Spying

In March 1997 I issued a civil summons against the BBC, seeking injunction against further "newscaster spying", and token damages for what the BBC had done to me until that date. The purpose of the summons was to try to "smoke out" the BBC, since obviously I did not have good evidence which would be necessary for either a civil or criminal case to be made against them. My summons was worded as follows;

1. The plaintiff is and was at all material times residing at [home address]. At some time prior to or during June 1990, persons of unknown identity entered Plaintiff's premises and installed concealed television equipment in said premises.

2. A campaign of harassment was launched against the Plaintiff by the persons of unknown identity, which in part took the form of instigating harassment by BBC TV newscasters (including specifically Michael Buerk and Martyn Lewis) as they read news bulletins, by making direct and personal comments to Plaintiff.

3. The campaigns purpose was to subject Plaintiff to great mental stress and induce mental breakdown. As a result of it Plaintiff did indeed suffer from severe mental strain in 1990-97.

4. In order to avoid the mental strain being caused to him the Plaintiff has been compelled to stop watching BBC TV news. Defendant therefore committed the tort of private nuisance, since normal use of home was interfered with.

5. Plaintiff claims a permanent injunction prohibiting further nuisance, and damages for nuisance suffered limited to 5,000.

Naturally, my attempt to smoke-out the BBC and its lying newscasters failed. The BBCs litigation department sought to have my summons struck out; and they succeeded in doing so, on the grounds of my action "disclosing no reasonable cause of action". I was also prevented from issuing further civil claims against the BBC without leave of the Court. Apparently litigants-in-person frequently / usually have their claims struck out with this wording, regardless of the merit of their claims.

BBC Suppresses my Claims of "Watching by Newscasters"

BBCs staff magazine Ariel ran my advert "BBC Newsreaders Spying on my home" for one issue in the Personal category on 8/July/1997 before it was spotted and axed by editor Robin Reynolds; please see webpage; http://www.pair.com/spook/evidence/plaint/ariel.htm
Clearly the BBC will not allow claims of its wrongdoing to be made public in the media channels it controls.

On several occasions people said to my face that harassment from the TV was happening. On the first day I worked in Oxford, I spent the evening in the local pub the Rose and Crown with the company's technical director Ian, and Phil, another employee. Ian made a few references to me and said

to Phil, as if in an aside, "Is he the bloke who's been on TV?" to which Phil replied, "Yes, I think so".

The reader might think that mere "watching" by newscasters etc might be a relatively benign happening. But it is not; it is part of MI5s framework of harassment and lies. On many occasions the reactions of the BBCs newscasters to me has been in the nature of sarcasm, implicit contempt and abuse. This is visible in Witchells news programme mentioned above, where he engages in abuse by laughing at me during his newsreading. It was particularly visible in the early period of 1990-92, and as late as Autumn 1993, when during a Newsnight broadcast Jeremy Paxman interviewed a football person about soccer hooliganism, and the interviewee gave vent to an unsubtle rant about "theyre idiots, theyre just idiots, keep up the surveillance". Paxman started grinning, showing he understood and was taking part in the abuse being perpetrated on that programme.

Conclusion

The MI5 Persecution started with harassment by television newscasters, and today harassment by TV and radio presenters still forms a key part of MI5s activities against me. When this business started in June 1990 I was in relatively good health of mind. Years of persecution by the secret police and their mouthpieces in the state-run BBC and other media eroded my health until MI5 achieved their aim of seeing me rendered mentally ill in November 1992. The diagnosis which was forced on me unfortunately and ironically meant that my reports of the harassment are disregarded, because the mentally ill are second-class citizens in todays Britain.

Yet TV and radio harassment continues, albeit in a reduced form, despite my taping all the programmes I watch, resulting in my being able to obtain and demonstrate objectively on the website instances of media presenters attacking me. Unfortunately these recorded instances are quite tenuous; I might understand them, the presenters understand what it is theyre doing, but despite many thousands of people knowing the truth of the "newscaster watching", the omerta continues and they continue to refuse to admit the truth of the matter. It is a terrible indictment of British society that there is not even one decent person willing to speak out. I look forward to the day when the truth does finally emerge, and the mass corruption which has allowed the MI5 persecution to take place is finally purged and the Establishment criminals caught and appropriately punished.

MI5 Persecution: Molestation during Travel

MI5s persecution of me varies in intensity. Since 1990 it has been steady for perhaps 80% of the time; there was a notable quiet period in 1993, and another quiet period in Jan-Feb 1995, as well as a hiatus in the first two months of 1999. It puzzles me that they cease and restart, seemingly without any logic or reason. But one aspect of MI5s activities against me which is relatively predictable is this weeks articles topic, which is Molestation during Travel. Almost every time I cross the Atlantic, go to the Continent or even try to enjoy a holiday in this country, you can bet that MI5 will be there doing their utmost to wreck it all.

This aspect of the harassment is particularly relevant as I will be travelling to Europe again in a months time, with naturally the Minidisc recorder in tow; so it will be interesting to see if I can record the abuse which will almost certainly take place, either on the Tube going to the airport, at the airport, on the flight, in the terminal building - MI5 have previously instituted instances of abuse at each of these locations, so well see how much taxpayers money they waste this time, and whether it will prove possible to capture their abuse on minidisc.

Read about the MI5 Persecution on the Web

June 1992 in Polands mountain resort of Zakopane

The persecution started in June 1990, and for the first two years I stayed in the UK apart from a couple of brief day trips to Calais. By the summer of 1992 Id had enough of being cooped up in England with abusive fellow employees egged on by an abusive secret police service, and decided to spend 10 days in southern Poland, on what was intended to be a holiday at the mountain resort town of Zakopane.

Unfortunately the psychopaths of the Security Service were not willing to allow me to enjoy a holiday in peace and quiet. The journey to Zakopane was by coach from the meeting point at Londons Victoria coach station (National Express) followed by ferry followed by another coach across Europe. As we left Victoria a youth and his girlfriend started a loud tirade of abuse directed at "this bloke", where the "bloke" was never named, but it was very clear that the "bloke" was myself. The youth said "they" had "found somebody from his school, and he was always really stressed at school, a real psycho". Again, the label "they" was not elaborated on, but it was clear that "they" = the persecutors from MI5. The boy also said, "he was in a bed and breakfast for only one night and they got him". By a not unexpected coincidence I had been in a B&B in

Oxford a week previously, which had been booked from work; other things lead me to the conclusion that the company's offices were bugged for most of the 2 1/2 years that I was there, so "they" would have known a room in the B&B had been booked. After a few minutes of this I went back to where they were sitting and asked where they were travelling. The boy named a village in France, and the girl's giggling suddenly ceased; presumably it permeated to her brain cell what the purpose of the boy's abuse was.

It is now very clear to me that MI5 were trying to have me incarcerated, assaulted or killed on this trip across Europe. The degree of verbal violence inescapably leads to this conclusion. When we arrived at our destination, it became clear that many people, both in our tour group and its guide, and among the ordinary residents of the town, knew there was a movement under way to "get" me. MI5 employed many people and significant resources for an action which they knew would only take a maximum of ten days. A commercial operation would never have felt able to waste such resources on such an unproductive and temporary action; only a state-sponsored, taxpayer-funded entity like the Security Service would be able to be so wasteful.

To give some examples of what happened in those ten days; I was walking in some woods outside the town, when a Polish woman, looking at me, said the English "shit" in a strongly Polish-accented voice. For the first three years 1990-92 MI5 had been trying to force this word on me. Another example; I was walking near my "hotel" when a mother said laughing to her child, "a wiesz ze to prawdziwy wariat" which means "you know hes a real madman". And the "TV reacting" happened there too; on Polish TV, a bemused looking journalist said to another, "to jest sprawa Anglikow", which means "its the concern of the English", in other words, none of our business, despite what the English are trying to force down our throats.

Just before we left for home, I went with some others from our group to a nearby bar. There a man shouted at me the same sexual obscenity which MI5 have constantly thrown at me these last three years. I think MI5 try to justify their various terms of abuse by repeating them at me until I say them, either while conscious or while talking in my sleep; and then they seize on my saying those words to "prove" that the obscenities are "my fault", et cetera. This rather stupid reasoning of theirs can actually be seen as indicative of the psychopathic condition attributed to them in a previous article; blaming the victim for the crime you inflict on him is how psychopaths think.

Nor did the persecutors let up during the return trip. Returning on the ferry over the channel, a rather insalubrious-looking guy talked to his mates about "and you know this bloke, hes really mad you know, hes really mad". On the National Express return coach to London, a group of five or six young people started shouting at me. I slumped in my seat and tried to avoid presenting a target, so they got ever more strident - "whats the matter with you, cant you hear us?" One of the other people who had been on the trip to Poland asked them why they were shouting at me, and they said, "hes been to Cambridge", to which the co-holidayer asked them, "have

you been to Cambridge?" presumably thinking they were aggrieved fellow students, but they answered "no". Even after I left the coach at Elephant and Castle abuse continued; in the tube station, two kids started throwing abuse at me; one of them said to the other, "and you know he works?" to which the other answered "yes".

Immediate Aftermath of November 1992

As you will know from previous articles, my manager at OCG - ARIS/Oxford, Mr Mitchell, induced a mental breakdown in me in the months leading up to Nov/92. The diagnosis was regarded by the persecutors as a victory for them, because few if any people give credence to allegations of harassment when they are made by somebody suffering from schizophrenia. There is also a bias against the mentally ill, an "institutionalised bigotry" in society comparable to the institutionalised racism against blacks.

However, MI5 did not let up on persecuting me following Nov/92. In December 1992 I flew by charter jet to Alicante in Spain for two weeks recuperation. MI5 planted one of their people on the flight, a youth who tried to start some noises that "hes a nutter". One of the other passengers replied, "oh hes a nutter is he? oh well!" and the youth shut up and said nothing for the rest of the flight. I think it would be fair to say that the youth on the flight was embarrassed by what he had been asked to do in making the flight "uncomfortable" for me; he sounded defensive rather than aggressive.

My first trip to Canada in June 1993

Ive already covered this in a previous article so Ill just give a brief summary here. On 10 June 1993 I flew British Airways from Heathrow to Torontos Pearson Airport. On de-planing from the aircraft, one of a group of four fellow passengers looked at me and said, laughing, "if he tries to run away well find him". It was quite obvious that these four men were the ones who had been harassing me since 1990.

I did nothing to apprehend them or bring this incident to the attention of the airport authorities, mostly because this was my very first visit to Canada, and the last thing I wanted was to get into a dispute before I had even finished disembarking. In retrospect, I can see this was a terrible mistake; I should have made every effort to detain and identify these people.

Subsequently I have made numerous attempts to obtain the names of these people from British Airways passenger lists, by talking to BA, through a lawyer in Ontario, through a solicitor in England, through the UK police, and also through private detectives in the UK. But all my efforts have come to nothing. BA have told me they keep passenger lists for a period of seven years, so they will still have the list for this 1993 flight. I did not see or hear anything during the rest of my visit to Ontario in 1993 which would have lead me to believe that I was being watched or followed.

Journey across Canada in summer 1994

As I think Ive already said in previous articles I emigrated to Canada in late May 1994. For six weeks between late May 1994 and early July 1994 I travelled across Canada from coast to coast, starting in Toronto, visiting various cities and ending up in British Columbia. I saw this both as something of a holiday, and the chance to get to know a little better my adopted country.

As you can guess, MI5 followed me everywhere I went during these six weeks. In Toronto, where I started this trip in late May, I was spoken about by one youth to another with the words "hes an idiot", to which the other replied, laughing sympathetically, "good luck to him".

A couple of days later I went to Montreal and stayed at the YMCA downtown. As you can guess (this is all so predictable, isnt it?) MI5 followed me there and bugged my room at the YMCA. Not only that, but they managed to set-up an instance of "newscaster reaction" from a local television station; while I was watching a Vermont TV news programme on the set in my room, the woman reporter said, "well theyre just tired and they want to go home", which sounds like a pretty unprofessional thing to say until you realise she was trying to say of me that I was the one that was supposed to be tired, and they (ie MI5) wanted me to go home to the UK.

On the bus journey across the North American continent, it was quite clear that MI5 were following me every step on the way. For the first part of the journey they actually put someone on the bus with me, a youth who said at me "that guys paranoid" and tried to incite other passengers to attack me. I stopped for a couple of days in Winnipeg in central Canada, and on leaving the town heard on the radio a female presenter ranting about "insanity! insanity!". It is very tiring travelling such a long distance by bus; I took the journey in two steps, each of about 36 hours; and it is especially tiring when you know MI5 are watching you and harassing you every step of the way.

When I finally got to Vancouver, MI5 instituted the usual harassment, in very short order. I was surprised how quickly they were able to induce hatred towards me in elements of the general populace; the Security Service must have employed a number of agents and serious resources in a very short period of time; and for no real gain, because I havent been back to BC for almost five years, so all their "work" appears to be for nothing. In downtown Vancouver a street person said in front of me, "theyre all talking about him". For a few days I was staying at Pauls Guest House (345 W.14th Ave); on the day I left, the owner Paul shouted at no-one in particular, "hes going to Victoria" - which was quite accurate, I was indeed going to the provincial capital Victoria on Vancouver Island. But I had not told anyone at the guest house where I was going; I had only mentioned to my parents back in England on the phone that I was going away from Vancouver for a few days. Which leads me to suppose that MI5s bugging of the phone in my parents house yielded the "intelligence" that I intended to visit Victoria, and they had passed the information on to Paul.

When I got to Victoria it was again obvious that the persecutors were "doing their stuff" there as well. On the street I was identified as being English, although I had not said anything so my accent hadnt given me away; and returning by ferry to the mainland, I was abused by a Canadian woman who said, "hes a nutter! you can run but you cant hide". During my years in Canada I have never heard the word "nutter" on any other occasion; I do not think it is part of Canadians vocabulary; so the Canadian woman on the ferry, who was obviously talking about me, must have been supplied with this word by the English persecutors. And once I got back to Vancouver, staying at the Austin Hotel on Granville St, I listened to a conversation in the apartment block directly opposite, and a man saying, "hes paranoid, so thats as bad as it can be, so why are they doing this to him?".

Holiday in the States, August 1995

By 1995 I was living in Canada, and in August I went down the eastern seaboard to Florida and as far as Key West by car. As you can guess (this is all so boring and predictable, isnt it?) MI5 followed me every step of the way. I can see in retrospect that this must have been quite easy for them as they had my car bugged, both on the inside to listen to anything that was said and what radio station I was listening to, as well as what must have been a tracker device installed to track it across long distances.

The first city I visited was Philadelphia. In the old Congress Hall where the first US Congress assembled, the woman guide started referring to my situation, saying that "all these people in Europe were watching it", and they were "a little paranoid" at this 18th-century experiment in democracy. Also I had recently written a newsgroup post where Id described a (female) poster as "wet-nosed" (implying "canine"), and a young girl in Philadelphia remarked, "so he thinks were dogs?" There were two or three more incidents during this holiday in the eastern States, including a radio station down near Miami, showing "they" had tracked me all the way there, and were bugging the inside of my car; but I didnt record the details and Ive forgotten some of it now. Also down in Miami Beach a French tourist in a lift expressed support for me with the words, "cest incroyable" ie. its incredible, meaning that MI5s well-known actions against me were beyond belief.

To go back a bit, in about May/June 1995 Id visited New York, again by car, and was insulted several times by people using the same words that had been used against me in England. In Central Park, and elderly Englishman (not a real gentleman - but then the Engish view of themselves as "gentlemen" etc is quite laughable) looked at me and said "idiot". And while I was eating in a streetside restaurant a New York youth started laughing and said something like, "I cant believe it, hes actually here" - I think that was because I had had an expressed wish to visit New York for some years before this, although after this visit I wont be going there again for a very long time.

Visit to Poland December 1995/January 1996

In December 1995 I flew (BA again, unfortunately - every time Ive flown BA one of these incidents has happened, presumably MI5 is happier setting up harassment on British-domiciled carrier) from Montreal to Berlin and travelled on to Poland to visit family. MI5 naturally harassed me in Poland during my brief stay. They followed me around and got Polish people to take part in the harassment. In one case two Polish youths talked in front of me saying in English (with marked Polish accents), "fucked up men, fuck you". There were also other incidents which I dont remember too clearly since it was some time ago.

The return flight connected through Heathrow, and in the transit lounge MI5 again set-up harassment against me. In Poland they were talking their abuse in English, and in London they set Polish people after me to speak in Polish; they heard me on the phone to my father, and said "a wiesz ze to Polski wariat", in an almost sympathetic, inclusive fashion (translation. "you know hes a Polish nutter"). Once on the flight to Montreal I was again set upon by two English youths, one of whom spoke and the other listened. The aggressive "fat bastard" youth said, "if he wants to be a wanker" (its my fault theyre harassing me, you see), self-justification that "hes a nutter" (so we have to keep on abusing him, because hes ill), as well as talking about the town in Poland where I had been staying. He also said, "he doesnt know who we are", but as already remarked in a previous article, that was at best a half-denial of my guess expressed in internet newsgroups that the people after me were MI5 - if anything its a half-confirmation rather than a half-denial.

These incidents are still going on. You can hear digitised audio files of abuse on a BA flight to Berlin in 1998 on the Web at address

On this flight they were again attacking my mental health; "paranoid, hes paranoid" and "nutter" are discernable. The last "during travel" contact was at Ottawa Airport on 21 July 1998, when "Alan Holdsworth" the psychopath MI5 agent, dressed as a vagrant, was pacing aggressively in the departure area. In three weeks I will again be travelling to Europe; we will see what fresh acts of molestation MI5 perpetrate during this trip.

3492. MI5-Persecution: MI5 are Afraid to Admit Theyre Behind the Persecution (27125)

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-16 16:54:50 UTC

MI5 are Afraid to Admit They're Behind the Persecution

MI5 have issued a formal denial of any involvement in my life to the Security Service Tribunal, as you might expect them to; but, more importantly, the persecutors have never denied that theyre from the Security Service, despite several years of accusations from my corner on usenet and in faxed articles. I am not surprised that the Security Service Tribunal found "no determination in your favour". I am however a little surprised that the persecutors have refused to confirm my identification of them; by doing so, they implicitly admit that my guess was right.

"No determination in your favour" says the Security Service Tribunal

In 1997, I made a complaint to the Security Service Tribunal, giving only the bare outlines of my case. I do not think it would have made very much difference if Id made a much more detailed complaint, since the Tribunal has no ability to perform investigatory functions. It can only ask MI5 if they have an interest in a subject, to which MI5 are of course free to be "economical with the truth". A couple of months after my complaint the Tribunal replied that;

The Security Service Tribunal have now investigated your complaint and have asked me to inform you that no determination in your favour has been made on your complaint.

Needless to say this reply didnt surprise me in the slightest. It is a well established fact that the secret service are a den of liars and the Tribunal a toothless watchdog, so to see them conforming to these stereotypes might be disappointing but unsurprising.

It is noteworthy that the Tribunal never gives the plaintiff information on whether the "no determination in your favour" is because MI5 claims to have no interest in him, or whether they claim their interest is "justified". In the 1997 report of the Security Service Commissioner he writes that "The ambiguity of the terms in which the notification of the Tribunals decision is expressed is intentional", since a less ambiguous answer would indicate to the plaintiff whether he were indeed under MI5 surveillance. But I note that the ambiguity also allows MI5 to get away with lying to the question of their interest in me; they can claim to the Tribunal that they have no interest, but at a future date, when it becomes clear that they did indeed place me under surveillance and harassment, they can claim their interest was "justified" - and the Tribunal will presumably not admit that in their previous reply MI5 claimed to have no

interest.

"He doesnt know who we are"

In early January 1996 I flew on a British Airways jet from London to Montreal; also present on the plane, about three or four rows behind me, were two young men, one of them fat and voluble, the other silent. It was quite clear that these two had been planted on the aircraft to "wind me up". The fat youth described the town in Poland where I had spent Christmas, and made some unpleasant personal slurs against me. Most interestingly, he said the words, "he doesnt know who we are".

Now I find this particular form of words very interesting, because while it is not a clear admission, it is only a half-hearted attempt at denial of my guess that "they" = "MI5". Had my guess been wrong, the fat youth would surely have said so more clearly. What he was trying to do was to half-deny something he knew to be true, and he was limited to making statements which he knew to be not false; so he made a lukewarm denial which on the face of it means nothing, but in fact acts as a confirmation of my guess of who "they" are.

On one of the other occasions when I saw the persecutors in person, on the BA flight to Toronto in June 1993, one of the group of four men said, "if he tries to run away well find him". But the other three stayed totally quiet and avoided eye contact. They did so to avoid being apprehended and identified - since if they were identified, their employers would have been revealed, and it would become known that it was the secret services who were behind the persecution.

Why are MI5 So Afraid to admit their involvement?

If you think about it, what has been going on in Britain for the last nine years is simply beyond belief. The British declare themselves to be "decent" by definition, so when they engage in indecent activities such as the persecution of a mentally ill person, their decency "because were British" is still in the forefront of their minds, and a process of mental doublethink kicks in, where their antisocial and indecent activities are blamed on the victim "because its his fault were persecuting him", and their self-regard and self-image of decency remains untarnished. As remarked in another article some time ago, this process is basically the same as a large number of Germans employed fifty years ago against Slavic "untermenschen" and the Jewish "threat" - the Germans declared, "Germans are known to be decent and the minorities are at fault for what we do to them" - so they were able to retain the view of themselves as being "decent".

Now suppose this entire episode had happened in some other country. The British have a poor view of the French, so lets say it had all happened in France. Suppose there was a Frenchman, of non-French extraction, who was targeted by the French internal security apparatus, for the dubious amusement of French television newscasters, and tortured for 9 years with various sexual and other verbal abuse and taunts of "suicide". Suppose

this all came out into the open. Naturally, the French authorities would try hard to place the blame on their victim - and in their own country, through the same state-controlled media which the authorities employ as instruments of torture, their view might prevail - but what on earth would people overseas make of their actions? Where would their "decency" be then?

This is why MI5 are so afraid to admit theyre behind the persecution. Because if they did admit responsibility, then they would be admitting that there was an action against me - and if the truth came out, then the walls would come tumbling down. And if the persecutors were to admit they were from MI5, then you can be sure I would report the fact; and the persecutors support would fall away, among the mass media as well as among the general public. When I started identifying MI5 as the persecutors in 1995 and 1996 there was a sharp reduction in media harassment, since people read my internet newsgroup posts and knew I was telling the truth. The persecutors cannot deny my claim that theyre MI5, because then I would report their denial and they would be seen as liars - but they cannot admit it either, as that would puncture their campaign against me. So they are forced to maintain a ridiculous silence on the issue of their identity, in the face of vociferous accusations on internet newsgroups and faxed articles.

Have MI5 lied to the Home Secretary?

In order for the Security Services to bug my home, they would either have needed a warrant from the Home Secretary, or they might have instituted the bugging without a warrant. Personally I think it is more likely that they didnt apply for a warrant - I cannot see any Home Secretary giving MI5 authority to bug a residence to allow television newscasters to satisfy their rather voyeuristic needs vis-a-vis one of their audience. But it is possible that the Security Service presented a warrant in some form before a home secretary at some point in the last nine years, for telephone tapping or surveillance of my residence, or interception of postal service.

So the possibility presents itself that a Home Secretary might have signed a warrant presented to him based on MI5 lies. Just as MI5 lie to the Security Service Tribunal, so they might have lied to a Home Secretray himself. MI5 and MI6 are naturally secretive services former home secretary Roy Jenkins said, they have a "secretive atmosphere ... secretive vis-a-vis the government as well as [enemies]". Jenkins also said he "did not form a very high regard for how they discharged their duties".

It was only a few years ago that MI5 was brought into any sot the extraordinary thing is that British media organisations like the state- and taxpayer-funded BBC take such an active part in the MI5-inspired campaign of harassment. We have after all heard of MI5 trying to bribe broadcast journalists; but surely there must be a substantial number who are not bought or blackmailed by the Security Services, and who take part in the "abuse by newscasters" of their own volition? The BBC is supposed

to be independent of the government of the day as well as the Establishment in general. While perhaps it is childish to think that the BBC is anything other than effectively state-controlled, the degree of collusion between the BBC and the British Secret Police MI5 is something you would not find in many countries. Individual tele-journalists in other countries would have enough self-esteem not to allow themselves to be controlled by their secret police - seemingly, BBC broadcasters like Martyn Lewis and Nicholas Witchell have such a low opinion of their employing organisation that they see no wrong in dragging the BBCs no-longer-good name through yet more mud, at the mere request (whether supported by financial or other inducements) of the British secret Police, MI5.

And when challenged, these broadcasters LIE about their involvement, with just as little shame as MI5 themselves. The BBCs Information dept have said that;

"I can assure you that the BBC would never engage in any form of surveillance activity such as you describe"

which is an out-and-out lie. Buerk and Lewis have themselves lied to their colleagues in the BBCs Information department over the "newscaster watching", but unsurprisingly they refuse to put these denials in writing. Doubtless if the "newscaster watching" ever comes to light, Buerk and Lewis will then continue to lie by lying about these denials. So much for the "impartial" BBC, a nest of liars bought and paid for by the Security Services!

It is obvious that the persecution is at the instigation of MI5 themselves - they have read my post, and only they have the surveillance technology and media/political access. Yet they have lied outright to the Security Service Tribunal. Similarly, BBC newscasters Michael Buerk and Martyn Lewis have lied to members of their own organisation. The continuing harassment indicates they are all petrified of this business coming out into the open. I will continue to do everything possible to ensure that their wrongdoing is exposed.

MI5 Persecution Update: Friday 11 June, 1999

Harassment in a pub in Clapham, Tuesday lunchtime

Once a month, or once every other month, I meet a Polish friends of mine who lives in Clapham North, and sometimes we go to a particular pub near where he lives. The last time was some two months ago; I did not have my minidisc-walkman with me, and consequently was seriously harassed by people MI5 had instructed to harass me, in the pub.

This Tuesday, 8 June 1999, we again went to the same pub for a pre-meal drink. This time I did have my minidisc-walkman with me. As you can guess, we were followed into the pub by a couple of young people (Im getting older and older - isnt it funny how the MI5 agents all look young these days?). They started talking about my situation, in particular some travel I had booked the previous day. Unfortunately, they were talking fairly quietly, and my minidisc didnt pick up their speech.

MI5s schizophrenic reasoning is that simultaneously I am very important and worthy of their acts of persecution, and I am also totally unimportant and their abuse of me "doesnt matter". Perhaps they should test their agents and managers for obsessive personalities or psychotic features in the same way as employees are drug-tested. MI5 might lose their "worst cases" employees if some psychological testing were applied to their recruitment procedure.

Toothless Watchdogs. What a Surprise.

Recently I have been engaging in communications with two watchdogs, the Security Service Tribunal which deals with complaints against the security service (and always clears MI5 of any wrongdoing), and the Data Protection Registrar, which is mandated to investigate misuse of personal data held on computer.

In a letter to Nick Brooks, Security Service Tribunal secretary, dated 20 April, I asked him if the Tribunal, as an allegedly independent body, had the means to investigate complaints against MI5 other than asking MI5 to themselves investigate complaints. To my disappointment, his reply two weeks later answered the question only indirectly, in the negative. Whatever the reader might think of the merits of the case I have been putting before you in faxed articles this last year and half, you will surely recognise that it is a significant anomaly for the Tribunal to have no independent means of investigating complaints, particularly given the view expressed even by previous home secretaries that the security

services are untrustworthy.

MI5 Persecution: No Justice for the Victims of MI5

In a previous article I detailed the similarities between the current MI5 Persecution in England, and other historical instances of similar persecution, notably that by the Nazi Germans in the thirties and forties. The Germans persecuted first the mentally ill, the epileptics and those suffering from schizophrenia, then moved on to racial groups; in todays Britain the persecution is again directed at those with mental illness, which the British in their cowardice find easier than taking on racial groups as the Germans did. But just as in Thirties Germany there was no recourse against a malign and omnipotent state, so the MI5 Secret Police in the modern British Fascist State allow no justice for their victims.

No Recourse Against the Security Services Illegal Harassment

It has become apparent to me over the last nine years just how loaded the dice are in todays Britain, a fundamentally fascist country which masquerades as a democracy. Britain is a democracy in name only; the Establishment, the defence and MI5 secret police are always there, regardless of which party has been voted into power most recently - and from "New Labours" conduct in office one finds it difficult to tell them apart from Old Tories, in their crackdowns on the sick and vulnerable in society.

In thirties Germany the victims of the Nazi regime had no legal recourse against their State oppressors; and in todays Fascist British state, the victims of the Establishment and its MI5 Secret Police similarly have no recourse against the illegal state-funded and organised oppression. There is supposed to be a mechanism for dealing with MI5 crimes, in the shape of the Security Service Tribunal and Commissioner; yet these have never found favour of a plaintiff. One might as well ask the Nazi SS to investigate crimes against epileptics or Jews as ask the Security Service Tribunal to investigate MI5 crimes against British citizens; it is quite obvious what the answer is going to be, regardless of what you say to them, and what evidence you provide. The Tribunal and Commissioner are a mere formality, a whitewashing body to give the Secret Services a veneer beneath which they hide their shabby criminality.

"Institutional Racism" and Bigotry in the Metropolitan Police

The recent inquiry into the racist murder of Stephen Lawrence found clear evidence of systematic and deliberate racism in the Metropolitan Police, which cannot have surprised anyone. Commissioner Sir Paul Condon accepted a somewhat lukewarm definition of institutional racism as being "unconscious". In truth, and this truth must surely be obvious to anyone who has any familiarity or encountered the great British police, the Met has not just "unconscious" racism, but very clearly "conscious" and deliberate racism, of the kind that would have done Thirties Germans proud. And it is a bastion of such open racism - when many other parts of

society are learning to live in a multicultural environment, the Met is still living in the past in its attitude to the minorities.

But in addition to the systematic racism confirmed by the Lawrence inquiry, there is also something much more relevant to this case, which is systematic police bigotry against the physically and mentally disabled, which I personally have experienced in my dealings with the police over the years. You cannot expect equal treatment if you are mentally disabled. I tried to make a complaint to the police in 1995 about the harassment I had been subjected to for several years. As soon as they found out I had mental illness, they refused to even talk to me. I tried again in March 1999; the police made various threats to me, while ranting about "your paranoid rubbish" in reference to the complaints expressed to them.

The police refusal to do the job they are employed and paid to do is extremely serious, particularly as this case is highly important, indeed key to the whole issue of British self-perception at the end of the 20th century and the beginning of the 21st century. Britain has lost much in the last fifty years - it has lost an empire, it has lost its self-respect and its identity as a people. If the MI5 persecution finally makes it into the light and the Security Services are seen for the rather cheap bullies their behaviour indicates, it will have a massive and harmful effect on British self-perception in the new century.

Security Service Tribunal - Blatant Whitewashing

A few weeks ago I spoke on the phone to Nick Brooks, the Secretary of the Security Service Tribunal, which is supposed to deal with cases of MI5 transgression. I asked him if the Tribunal had ever found in favour of a plaintiff and against the Security Service. He answered that as far as he knew, it had not.

I also asked Mr Brooks if the Tribunal had any means of investigating allegations of criminal activity by MI5, other than asking MI5 themselves if they had engaged in such activity. His rather circuitous written reply states that the 1989 Security Service Act provides that "it shall be the duty of every member of the Service to disclose or give to the Tribunal such documents or information as they may require for the purpose of enabling them to carry out their functions under this Act". Which is a very round-about way of saying - "No" - the Tribunal has no way of investigating MI5 crimes - None At All.

Setting up the S.S. Tribunal, and creating a Security Service Commissioner, was really an act of falsehood by the government. It is generally recognised that MI5 are out of reach of the normal criminal justice system - the police, as we have seen, have no intesot answer to the government; in a previous article I quoted Roy Jenkins speaking of "a secretive atmosphere.... secretive vis-a-vis the government as well as [enemies]", and a "lack of frankness" from MI5.

If the government wanted to, it could reform the secret services and ensure they acted in conformance with the laws which have been enacted for them in the last ten years. But apparently the present government does not see any need to ensure security service compliance with the law. As noted above, the regulatory machinery for MI5 is deliberately weak; the Tribunal has no independent means of investigation, and it is simply a waste of time complaining to the Tribunal or Commissioner.

Every so often, fresh revelations come to light of secret service transgressions. We have heard from Shayler that MI5 bugged Jack Straw and Peter Mandelson; we have heard from Peter Wright that MI5 plotted to see Wilson ejected from office; yet so closed is the system of government that the law is never enforced against MI5 when they "bug and burgle" everyone from politicians to ordinary citizens.

No Justice from the Legal System, either

Britain has a civil and criminal justice system which effectively limits many complaints from being heard. For a civil complaint to be brought before a court, you need a solicitor willing to act on your behalf. Supposedly it is possible to represent yourself as a Litigant-in-Pthe basis of being "frivolous and vexatious" or "disclosing no cause for action in law". This is exactly what happened to me in 1997 when I twice tried to take the BBC to court for spying on me in my living room at home; my case was twice struck out, and on the second occasion an order was made against me that I could not bring further civil litigation against the BBC without leave of the court.

As the reader can guess it is quite impossible for a person with schizophrenia, who complains about the secret services and media interfering in his life, to find a solicitor willing to represent him in legal action against the persecutors. I have quite a lot of evidence of the continuing persecution which I have posted on the website, even if the evidence is quite tentative and perhaps open to varying interpretations. But I have tried several firms of solicitors; some of them have acted unprofessionally and abused me; all of them have refused to represent me. My psychiatrist gave me the name of the firm of Bindman and Partners in central London, and I have approached them twice. On each occasion they refused to accept my instructions. Plainly the problem with Bindmans, which they have admitted, is their bigotry against mentally disabled people; yet this is not just something that is wrong with Bindmans, it is something that is wrong with the legal system as a whole, since the legal system necessitates finding a solicitor willing to represent you in order to bring a case to court, but it does not have a mechanism for providing a lawyer in the case where no solicitor is willing to take on your case. So the British legal system is such as to prevent cases such as mine from ever receiving an airing in a court.

So much for the civil courts. But the criminal justice system is no better. Two years ago the Protection from Harassment Act came into force. But again, while the Act is all very well on paper, in practice it is unenforceable in my case, since it would require Police action to see the law implemented, and if the police cannot even be trusted to conduct a

murder investigation competently (in the Lawrence case), then what chance is there of their investigating complaints against the Security Service? Of course, it would be possible for me to personally issue proceedings through a private prosecution either against MI5 themselves, or against one or more of their media tools; but here we see the same problems as with the civil courts, because first of all I would have to find a lawyer willing to act on my behalf. Litigants-in-person do exist in the criminal courts, but the Attorney General can bring such a prosecution to an end by taking it over and entering a plea of "nolle prossequi"; and I suspect that if I were to bring a private prosecution against either MI5 or one of their media tools, then this is exactly what would happen.

So much for British justice. But if anything the wrongs that have been perpetrated on me by the British justice system are quite mild to what others have suffered. Others have been wrongly convicted based on police evasions and lies, and spent many years in jail based on false charges. I should count myself lucky that despite the best efforts of the MI5 secret police, I have not acquired any criminal charges or convictions; which shows that for all their resources and influence, and the clear imperfections in the British legal system, there are still limits on how much subversion MI5 can achieve.

The latest in a long line of injustices

A comment I heard during the recent scandal of the police mishandling of the Lawrence murder investigation is that "its not as if the police themselves murdered him". This is not a particularly wise statement to make about the case, since it could be argued that the four alleged murderers were aided in their crime by the expectation that the police would deliberately botch the investigation - which of course is exactly what the police did.

But in my case, this would be a completely inaccurate thing to say - since the MI5 secret-police have expressly been trying to nine years now to see an end put to my life, either by having me incarcerated and my liberty ended, or by forcing self-termination on me. It is exactly as if the secret police "themselves murdered [me]", since that is what their aim is in their campaign against me.

The public has heard of instances of police mishandling of cases, of police manufacturing evidence, lying in court, extracting false confessions to clear up crimes, et cetera. Various instances of extra-legal activity by the secret services have also come to light in the last few years. The unhappy truth is that what MI5 have been doing to me for the last nine years is really nothing out of the ordinary for them. To me it seems unbelievable that this sort of systematic campaign of harassment, which thousands and thousands of people in this country and abroad are well aware of, could exist for such a long period of time with the media maintaining "omerta". But my case is not the first such instance of persecution by the "British secret police", and judging by the lack of any real controls on MI5, I very much doubt it will be the last.

3494. MI5-Persecution: MI5 Have Systematically Destroyed My Life (31491)

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-16 18:00:57 UTC

MI5 Have Systematically Destroyed My Life

This is getting depressing. From the feedback Ive received, the recipients of these faxes are tired of hearing my complaints, and in truth I am tired of sending them. The reason I havent yet ceased sending faxes is because I cannot think of any other effective means of replying to MI5s actions against me, and I feel I have to do something to try to defend myself. Three/four years ago I got the MI5 harassment out of my system by posting about it on Internet newsgroups, and for a few months this tactic was quite effective - I received (and indeed still do today) support from newsgroup regulars, and felt I could make my voice heard and break the MI5 monopoly on access to the British media. But that was years ago, and today nobody gives a tinkers cuss about my internet posts - so I have sought to escalate matters by communicating directly with the politicians who allegedly say how this country is supposed to be run.

Of course, its quite expensive to keep up a campaign of fax messages for many weeks. Each set of faxes takes approx 50 hours to send over the weekend, and costs perhaps 35. My phone bill for the last quarter was 350. These figures are naturally insignificant compared to what MI5 have been spending against me over a similar period. It also takes a lot of time and energy to create a new article every week, and try and find new and fresh aspects and viewpoints on MI5s persecution of me. I am beginning to run out of both new topics and energy to write these articles.

So I have a suggestion to put before the MI5 persecutors who have been wrecking my life since 1990. In a few days time I will be going on holiday to Poland and Germany, for a couple of weeks. Previously, almost every time I have travelled by plane, or gone anywhere on holiday, the MI5 "wreckers" have been most assiduous in destroying these trips. My suggestion is; if MI5 leave me alone on this next trip, I will cease transmitting these articles. If, however, there are any clear instances of harassment (and I am very capable of recognising MI5 harassment when I see it), then I will make public these instances and publish any recordings I may make of them, and, unwillingly and unhappily, continue the articles.

Read about the MI5 Persecution on the Web

Keith Hill MP (Labour - Streatham), my elected representative, as ever refuses to help.

MI5 Refuse to Allow me to have a Normal Life

Its kind of difficult to contemplate having a normal existence when you know your entire house is bugged from top to bottom, for audio and, very unpleasantly, video; when your employment is systematically destroyed, over and over again; when every time you leave the country your travel is disrupted by MI5 plants on the plane yelling abuse at you..... you get the idea. I would like to have some semblance of a normal life, like my Polish and English friends do. But MI5 have made this impossible, and they have leached massive resources from the taxpayer to institute a life not worthy of the name on me.

A few years ago MI5 were very open about their aims in persecuting me. They were shouting "suicide" at me, both in Canada where I lived at the time, and during my occasional visits to London. You cant get much clearer than that. There have been instances as recently as a few weeks ago of this intention being voiced by their side; on 15 April 1999, a woman at the next ticket counter at the Royal Festival Hall said;

"it would kill it, you know, it would just be overkill... they can't stop can they"

meaning that "they" were trying to "kill it" i.e. me and they "cant stop". The audio file is at;

I wonder why they "cant stop". Nobody (who doesnt know already) believes my claims - so what difference would it make, if they were to "stop" persecuting me? Perhaps what this persons remarks indicates, is the depth of the obsession MI5 have with this case. They have chosen at random a person from the general population, and done their worst to ruin my life. What is wrong with these people, that they persecute a national of the country whose citizens they are supposed to protect?

No Chance of a Harassment-Free Job

Since the harassment started in 1990 I have had three jobs, the first near Guildford, the second in Oxford, and the third overseas in Canada. All three jobs have been systematically destroyed by MI5. It is so ironic that MI5 employs a team of agents, each well compensated for their efforts, to persecute just one person paid a mere fraction of what they get for their "work". In fact, it is a joke that MI5 is allocated resources for this sort of effort. If this area of government were run along commercial lines then MI5 would be very rapidly closed down, they produce nothing of any value, instead spending their time obsessed with the bugging and surveillance of their former employees like Shayler, dangerous subversives like Straw and Mandelson, and "threats to national security" like yours truly.

Applying for my first post university job

When I was applying for my first post-university job in the closing months of 1990, I found at two or three job interviews that MI5 had got there ahead of me. Interviewers knew what words to repeat from what had been said at my home recently; MI5 had supplied them with words to hurt me, and the "British secret police" were trying to wreck my job search and discourage me from joining the world of work. This and the continuing

harassment in the media and by the public meant that the search for a job took very much longer than it would ordinarily be expected to take for a person with my qualifications.

With my first job near Guildford came the knowledge that MI5 were doing everything possible to make me lose the job. Despite their efforts I managed to stay in work for ten unhappy months, during which they made very clear to me that they were bugging my workplace, my accomodation in Woking, my car, my home..... and they also made clear that they had "got to" my employer in Guildford.

Employment with Oxford

I was able to find a new job, with Oxford Computer Training Services (now ARIS/Oxford), quite quickly. But it became very clear, very quickly, that MI5 were treating this job the same as the first; they tried to get the other employees and in particular the managers to attack me. It was plainly MI5s intention that I be sacked fro this job. But I was not sacked; instead, after almost a year of abuse from OCTS managers, I was forced to seek medical help, and had to take two months off for medical leave. OCTS MD Hugh Simpson-Wells was motivated in keeping me on by the fear that if he sacked me, then I would take him to court for the treatment OCTS managers had meted out to me during 1992.

Emigration to Canada

When I emigrated to Canada in 1994, I did think that perhaps MI5 would leave me alone, given that I had made the effort to leave the UK and try to find a new life overseas. I could not see any reason why they would continue to harass me over in Canada. But clearly the MI5 agents had their salaries to think about, since continue to harass me they most certainly did, at my home in Ottawa, and by getting fellow employees to speak against me, as had happened with previous jobs in the UK.

MI5 are denying me a future in work

Former Chief Constable of Devon and Cornwall John Alderson had this to say regarding MI5's activities;

"MI5 is not under the same restraints as the police. They infiltrate organisations, people's jobs and lives. They operate almost like a cancer."

Currently I am on disability, and I can see that MI5 are denying me a future in work. It would be an insult to logic for me to return to work and find a job, in the knowledge that an entire team of MI5 agents, paid in total many times what I would be earning, would have the objective of seeing me "done down" in the employment, and ejected from the place of work. This situation is completely wrong and nonsensical - I would very much like to have a job, but MI5 are preventing me from even thinking about returning to work. The culture of secrecy in MI5/MI6 means there is no objective oversight of their expenditure, when external oversight and greater transparency might lead to wasteful and illogical operations such

as that against me being shelved.

Watched and Harassed at my Home and Accommodation

As you will know if you have been reading these articles, MI5 have watched and harassed me at my home, and at every accommodation Ive had since 1990. Theyve also watched me at neighbours houses in London, and at short-term accommodation such as hotels and bed-and-breakfasts. They have used the "words" gained from these watching activities against me, by passing these words on to other people such as OCTS managers for them to make clear that I am being watched where I live.

Harassed at rented rooms in Oxford in 1992

This was at its worst in 1992 in Oxford, where during the week I lived at rented accommodation in Oxford, and at weekends returned to my parents home in London. I was being severely harassed by managers at my place of work, OCTS; and it was clear from the things they said that they were being supplied by MI5 with details of my home life, that they were being supplied with words to repeat at me.

In 1992 I moved house in Oxford many times, living at a total of five rented accommodations in ten months. In January I started off living in a rented room at Headington near the ring road / A40 intersection; then when it became clear that house was being bugged, moved to a rented room in Botley, some miles away. It was at the house in Botley that I had an "interactive watching" experience with Martyn Lewis while he was reading the news; I threw a term of abuse at him; he first flinched, then gave a gsult of what I had just said, he was no longer "on my side".

So I moved house again. This time to a place in Cowley, near the Rover car works, where I stayed for a few weeks. Because of continuing harassment at work, I soon moved from this accommodation, to yet another rented room on Iffley Road. By this time I was very ill and being abused continuously at work. Again, MI5 followed me to the rented room on Iffley Road, and created new instances of "newscaster watching". There was a television in the room which I watched, and as you can guess the newscasters got at me when I was watching the television. Also once I was assaulted, if thats the word for what happened, on leaving the house; a youth grabbed me by the coat lapels, roughed me up a bit with various terms of abuse. I did not report this assault to the police, because what was happening to me at work was very much worse, and nobody seemed to think that that was worthy of being reported to the police. Later that day at work, Alex G, a fellow employee, said "I heard he was assaulted".... I had not told anyone at work about the incident that morning..... so once again it was made very clear that MI5 were watching my rented accommodation and giving information about what was going on there to managers at work.

So I moved house yet again in late autumn 1992, this time to a rented room in a large house on Woodstock Road. I stayed there for several weeks as the situation at work deteriorated due to OCTS managers abuse, until I was forced to take sick leave from work for two months and attend hospital as

an outpatient; at which point I gave notice on the room, and returned to London.

MI5 continued to harass me after the diagnosis of serious illness was made. As reported previously, they harassed me on a flight to Spain in December 1992; and in 1993, when I returned to live and work in Oxford, they again bugged my rooms, as well as my workplace, although the intensity of the harassment was very much less than in 1992.

Watched, followed and harassed in Canada

It dismayed me to find that MI5 would not leave me alone after I had settled in Canada. In January 1995 I rented an apartment at the Bayshore complex in Ottawas west end. For some weeks there was no sign of the "buggers". But then it started all over again. They first bugged my car, which had a car alarm installed - the alarm went off two or three times in a single evening, and the following day gave a signal that the car had been broken into. Then they bugged my apartment, and in particular they installed bugs on the phone line in my apartment.

In September 1995 I moved to a new apartment in Ottawas Bytown Market area, the restaurant and entertainment heart of Canadas capital. This proved a serious mistake. In the west end I had been fairly distant from the centre of town where MI5 concentrated their efforts at turning people against me. In the Market area it was much easier for the persecutors to motivate people to harass me, and over the next couple of years there were frequent instances of harassment by the general public.

From 1995 I had some Polish friends in Ottawa, and as the reader can guess, MI5 have spent much effort trying to break up this friendship. They supplied various things about my home life to these friends, for example where I was living in the Market, directly over the road were the studios of a music radio station, which you had to "look up" to see; and MI5 told these friends that I was "looking up" to see the radio station; so the friends then replayed these words back to me, that I was "looking up". MI5 have also made various sexual slanders against me, and these friends also unwittingly replayed some of the words they had been imprinted with by the MI5 persecutors.

MI5 Will Never Allow Me to have a Normal Life

I have heard many excuses as to why MI5 continuously prevent me from having a normal life. We are told that MI5 are defending the country against a tere to zero.

When I have travelled abroad, they always put their people on the flights, on the journeys I undertake, to continue the harassment, so that I am put off further overseas travel, and chained to my home in London. Yet even this is illogical, because when I lived in Canada, they would still put people on flights back to the UK.... and what possible reason would they have for doing that? Perhaps the truest words to describe the MI5 persecution is that reason has nothing to do with their activities - sane people do not behave in the way the MI5 British Secret Police have been

doing.

Summer 1999 - more MI5 harassment?

In only a few days time I will be going to Europe again. This time I have deliberately chosen to travel by a non-UK airline; so we will see if they put their paid agents on this foreign carrier, we will see if they try to harass me on this non-British flight.

If they do harass me on this trip to Europe, or if they resume the harassment in London after I return home, then I will continue to report their activities in these faxes. As I said at the beginning of this article, I would very much like to not have to send these articles any more, but that is not my decision to make - it is entirely up to MI5 to cease their pointless persecution of me, once and for all.

I think that Vfor1 and Vref1 could also be understood to mean Vfor1 and Vrefsum, with Vrefsum being the sum of all the reflected waves occurring within the black box.

It strikes me that the concept of steady state AC is no different from the concept of DC discussed earlier in this thread. Steady state AC has no wave front to analyze. The impedance at the black box junction is a fact, not something that can be analyzed with steady state waves. I think you have said this a number of times.

The standing wave has no velocity, because we can not define a unit of the wave that moves. I think you have also pointed this out.

Wave fronts must be used if we want to look into the black box, or at least a MOVING sine wave so that we can look at the first reflection separately. I think this is what you have said many times, but I used different words.

If it was ever stated, I missed it. I suspect it was never
stated and some people jumped to false conclusions. I don't
think anyone is stupid enough to assert that the phase shift
in a capacitor is the same as it is in the absence of any
physical impedance discontinuity.

Continuing: What is the phase shift between Vfor1 and
Vfor2 for example:
(1) a capacitor with -j567 ohms impedance
(2) a 600 to 100 ohm dual-Z0 stub
(3) a single 600 ohm stub

I hope you are not going to tell us it's the same in
each case.

Capacitance is not obtained in a physical impedance discontinuity?
or is it:
Physical impedance discontinuity is not obtained from a capacitor?
or is it:
Could be either is inside a box, supplying only the terminals to
either; specifically either of which is indeterminate at a single
frequency where the terminals might present 43.4 degrees? (or any
suitable angle)

There are any number of stupid choices available. The question is:
Has your netzheimers progressed so far as to add another one?

At 800 postings, the odds must be distinctly favoring stupid.

Make it the daily-double:
Does a stupid math error make the answer valid?

When you acknowledge there is some confusion as to which phase is
being talked about. Do you suppose you know enough to tell us which
phase you are talking about?

More to the matter, what TWO phases do you suppose there are to be
confused between?

At 800+ postings, you could continue to sail right on past these
questions in your cloud of netzheimer bliss and leave us with a 50%
risk -um- chance; answer your challenge; and watching you trying to
sort it out. Again.

You missed the point. A terminating capacitor is a two
terminal network. The point where two pieces of feedline
are connected is a four-terminal network. A two-terminal
network is different from a four-terminal network.

Funny. In the part you deleated, I said it was the phase
shift between Vfor1 and Vfor2. Your sneaky underhanded
deletion trick is noted.
